the donor, the patient the donee, and the services rendered constitute the subject of gift. The services are rendered by the physician with the intent that they shall be gratuitous; the services being received, the gift is completed and perfect, whether the patient knew them to be gratuitous or thought them to be otherwise and expected to pay; for, to quote the words of Chief-Justice Sterrett, of the supreme court of Pennsylvania: "It is now too well settled to admit of question that, upon the ground of implied benefit, the assent of a donee will be presumed; and the title will vest *eo instanti* the gift is made, even though he be ignorant of the transaction, and will continue in him until he rejects it."* Moreover, if the services were intended as a gift when rendered, the physician can not subsequently change his mind and collect fees for such services even though it may have been through a misapprehension or mistake of facts that he was induced to originally intend the services as gratuitous.†

Whether or not it was the physician's intention that his services should be gratuitous is a question of fact which in the court of trial must be determined by the jury from the evidence submitted to them. All of the attending circumstances of the treatment, the relation of the physician and patient, the statements of the physician relative to compensation for such treatment, and the fact of whether or not the physician made a charge for such services at the time they were rendered, as shown by his books of original entry, are all circumstances to be taken into consideration in determining the intent.

Intoxication of Physician, Effect of, upon Right of Recovery.—A physician who attempts to render medical services when in such an intoxicated condition as to be unable to exercise proper skill and judgment is not entitled to any compensation for such services; but a patient who continues to employ a physician after he has rendered services in an intoxicated condition is not in a position to refuse paying his fee because of such past drunkenness.‡

Services among Physicians; Right to Compensation.—There is among physicians a custom to render services for each other without compensation. Whether or not this custom is sufficiently established and so generally understood as to defeat the right of a physician to compensation for services rendered to another physician has been considered by the supreme court of Georgia to be a matter of fact, which must be proved by evidence. If the evidence shows that it merely exists as a courtesy, and is not of universal observance, then the physician is entitled to compensation, unless, of course, there was an understanding or intention that the services were to be gratuitous. If, on the other hand, the evidence shows that the practice is so universal as to justify a physician treated in the belief that the custom becomes a part of the contract, then the right of compensation does not exist."

Carelessness in Regard to Contagious Diseases, Effect of.—It has been observed that a physician is bound to take such precautions as may be necessary to prevent the transmitting of a contagious disease from one patient to another. It naturally follows that if a physician disregards this duty, and a patient thereby

becomes afflicted with such contagious disease, the physician's right to compensation for services rendered to him is defeated to the extent of the damages suffered from the contagious disease.*

Promissory Note for Future Services Conditional.—Physicians sometimes undertake the treatment of a patient for a certain fixed fee or sum, and at the beginning of the treatment require the patient to execute a note for all or a part of the fee agreed upon. The consideration upon which such a note is based is the future rendering of professional services, and this class of services necessarily means personal services, and not the services of some assistant or other doctor; it therefore follows that if the physician entering into such a contract is from sickness or other cause rendered incapable of performing such services when due, under the contract the patient is relieved from his obligation to pay, and the note may be repudiated for failure of consideration.†

Partial Allowance by Municipality Extinguishes Claim against Patient.—A physician who attends a poor person under such circumstances as to bind the town or county for the payment is entitled to look for his compensation either to the municipality or to the patient; but if he presents his bill for such services to the municipality, and it is audited and allowed either at its face value or for a less amount, and the physician accepts the amount allowed, the indebtedness is completely extinguished both against the patient and the municipality. A case recently arose in New York involving this question. A physician rendered services to the value of eighty dollars. The patient being a poor person, he submitted the bill to the town "as health officer," and received twenty-five dollars. The patient subsequently performed services for the physician to the amount of twenty dollars, against which the physician proposed to offset his "balance" of fifty-five dollars. The supreme court was of the opinion that the trial court was authorized in finding from the facts that the physician's bill, interposed as a counterclaim, was for services performed for the town, and for which the town was liable. The court said: "The sum audited he accepted, and the effect of said transaction was necessarily to extinguish the claim against the town. If there was any liability on the part of the plaintiff (patient), as well as the town, for the defendant's (physician's) attendance upon his family, which defendant might have properly claimed, his presentation of the bill to the town, and acceptance of the amount at which it was audited, we think must have the effect of also extinguishing the claim against the plaintiff."‡

The judgment of twenty dollars in favor of the patient for services rendered to the physician was therefore approved and sustained by the supreme court.

Pith of Current Literature.

Death from Inhaling Nitric-acid Fumes.—Dr. H. S. Pearse (*Albany Medical Annals*, January) records the case of four firemen attending a fire caused by the

* *Tarr et al. vs. Robinson et al.*, 158 Pa. St., 60.

† *Pekelny vs. Starr*, 149 N. Y., 437.

‡ *McKeroy vs. Newell*, 73 Ga., 637.

" *Madden vs. Blain*, 66 Ga., 49.

* *Piper vs. Menifer*, 12 B. Monroe (Ky.), 465.

† *Powell vs. Newell*, 59 Minn., 406; 61 N. W. Rep., 335.

‡ *Wood vs. Munson*, 70 Hun., 468; 53 N. Y. S. R., 621; 24 N. Y. Supp., 287.

breaking of a carboy of nitric acid. The fire was quickly extinguished, and at the time none of the men felt any effects from the fumes of the acid; however, about six hours later, three of the men began to feel a rawness of the air-passages, and compression of the right thorax—one vomited a little; but those symptoms all disappeared within twenty-four hours. The fourth man, about the same time, complained of severe pains in chest, and difficulty in swallowing and talking. He walked three blocks to his home and was seen by Dr. C. H. Richardson and Dr. Pearce about 10.30 P. M.—eight hours and a half after inhaling the fumes. There was marked dyspnea; respirations were forty a minute, and very painful; voice husky; pulse 100, good quality; temperature elevation slight; pharynx very red; mucous membrane swollen; respiratory murmur high-pitched and harsh over bronchi and right lung, left lung not involved; some expectoration of bloody mucus. An unfavorable prognosis was given. Sedatives and neutralizing inhalations were prescribed. The patient was seen again early next morning; patches of consolidation had developed in the right lung with commencing oedema; there was slight cyanosis of the lips, finger nails, and ears; the pulse was rapid, but good in quality; the patient rational, but at 12 M., when moved to the hospital, he was slightly delirious. At three o'clock he became unconscious and very cyanotic; oedema was marked in both lungs, the left being less involved than the right; mucus slightly tinged with blood ran constantly from the mouth; the pulse was rapid and irregular; the temperature did not reach 101° F. (Oedema of the glottis being expected, preparations were made to meet it by tracheotomy. Stimulants and inhalations of oxygen were prescribed, and a pneumonia jacket and poultices applied to the chest. The patient died at 7 P. M., twenty-nine hours after inhalation of the fumes.

Dr. Pearce says that few similar cases have been reported, though numerous deaths have followed the inhalation of the fumes of this acid. The only peculiar feature in this case was the long delay in the development of the symptoms. The same peculiarity existed in the series, however. When a large amount is inhaled it is rapidly fatal—a broncho-pneumonia develops quickly, with subsequent oedema of the lungs, and death within twenty-four or thirty hours. Spasm of the glottis may occur immediately after inhaling the fumes and produce fatal asphyxia or oedema later, with the same result.

The Danger of Syphilitic Infection to Physicians.—Dr. L. Blake Baldwin (*Chicago Medical Recorder*, April) says that we, as physicians, hardly realize the danger of infection when examining patients, or the number of physicians that suffer from syphilis contracted in this way. Among forty-seven cases of extra-genital chancre reported by Fournier, thirty occurred in physicians and midwives. Dr. Blake can cite many cases in Chicago among physicians who have contracted syphilis in making examinations, performing obstetrical operations, making autopsies, dissecting, etc. After citing cases, he says that his experience with syphilis in physicians leads him to the conclusion that it is more serious with them than in the case of laymen, not because physicians are more susceptible to the syphilitic virus, but owing to the fact that from familiarity with the disease the physician either underestimates the danger and becomes careless in the treatment of his own case, or, in his anxiety to remove the manifestations of

the disease, he acts upon the advice of several of his colleagues at the same time, and thus becomes the victim of overmedication, to the detriment of his general health, and, owing to this lowered vitality, he becomes an easy prey to the disease itself. This conclusion has also been reached by Fournier in an article published in 1896.

Hydrochloride of Phenocoll in Grippe.—Dr. Giovanni Villani (*Gazzetta medica lombarda*, December 19, 1898) says that hydrochloride of phenocoll exerts a marked antithermic action in a period of time varying from half an hour to six hours. It is an excellent antiseptic, and a most useful antipyretic and analgetic in even the most severe and varied forms of neuralgia. It is easy of administration both to adults and children, the faintly salt and bitter taste being masked by syrup. The use of increasing doses is not necessary, as the organism does not apparently become habituated to it, nor is the excitability of the central nervous system diminished by its use. It is quickly absorbed and rapidly produces its effects, being constantly eliminated in the urine, its elimination beginning after twenty minutes, and being completed in from fifteen to twenty hours. In grave conditions and in young children this drug does not, the author says, produce either nausea, vomiting, collapse, or any other disturbance. It lowers the temperature in a regular and continuous manner, often producing slight cutaneous transpiration, more rarely sweating. It acts not only on the great nervous centres, the cerebellum and spinal cord, but also on their peripheral ramifications, producing a slight warmth in the head and flushing of the face. It determines, although not constantly, varying degrees of dilatation of the pupil, especially in somewhat large doses, the mydriasis persisting even after all other characteristic symptoms of phenocoll have disappeared.

The author lauds this drug, which may be administered in powder or in watery solution, either by the mouth or hypodermically, as a very valuable specific remedy for the treatment of influenza, having himself used it in upward of four hundred cases to his entire satisfaction. The amount used was from thirty to forty-five grains daily, administered in powders of seven grains and a half each for adults, and, for children, from fifteen to twenty-two grains and a half in solution in the course of twenty-four hours.

Bacteria and the Blood.—Dr. Franklin W. White (*Journal of the Boston Society of Medical Sciences*, February 21st), as a result of researches presented in the pathological laboratory of the Massachusetts General Hospital, summarizes his conclusions as follows: 1. Blood for bacteriological examination during life must be taken directly from the veins, and in considerable quantity. 2. Resorption of toxins is the most important feature of cases of sepsis; pyogenic bacteria invade the general circulation in a rather small proportion even of severe cases, and, as a rule, late in the course of disease. 3. A general infection by the pneumococcus can be demonstrated occasionally in the late stages of lobar pneumonia. 4. The value of blood cultures as a means of diagnosis in obscure cases of sepsis is limited by the fact that invasion of the blood by the specific organism can not be demonstrated during life in the majority of cases. Positive cultures are very valuable; negative cultures do not exclude local septic infection. 5. The detection of specific bacteria in the blood in cases of sepsis and pneumonia gives a very unfavorable prognosis in most cases. 6. General terminal infections

with pyogenic cocci occasionally occur as an immediate cause of death in chronic disease. Local infectious processes play this part more frequently. 7. As far as our experiments have shown, invasion of the blood by bacteria during the death agony, with subsequent distribution of the germs to the organs by the circulation, is a rather uncommon occurrence.

The Histopathology of Syphilis.—Dr. Maximilian Herzog (*Chicago Medical Recorder*, April) concludes a paper on this subject as follows: 1. As has long been known from clinical observations, syphilis primarily infects the lymphatic system and spreads by the lymphatics. 2. The infection of the blood-vessels occurs from the perivascular lymph spaces. The veins are less resistant, and consequently show the most marked changes, while the arteries, certainly in the earlier lesions, are not so prominently affected as the veins. 3. The specific living syphilitic poison is originally and probably permanently located in the lymphatic system, whence it invades the blood-vessels and leads to the appearance of general manifestations. After such a general outbreak there is established, either in consequence or independent of an antiluetic treatment, a hematogenous immunity. This latter, however, lasts only a limited period of time, when a new invasion of the blood-vessels from lymphatic foci may take place. Whether a final complete hematogenous and histogenous immunity may be established with the proper treatment or without it, is a question for discussion.

Salicylate of Sodium in Orchiepididymitis.—M. Pigot (*Gazette hebdomadaire de médecine et de chirurgie*, April 23d), in a thesis to the Faculty of Paris, considers salicylate of sodium superior to all other remedies employed hitherto in cases of orchiepididymitis where there is intense pain, but where the spermatic cord and the tunica vaginalis are but slightly affected. It does not act so well when the cord participates in the inflammation or when there is much swelling of the inflamed tunic. In the latter case the author recommends inunction of the cord with mercurial ointment and belladonna; while in the former, styphage, with or without puncture of the tunica, according to circumstances, is recommended.

A Forward Dislocation of the Sacrum.—M. Wilhelm (*Annales de chirurgie et d'orthopédie*, February) recently showed to the Medical Society of Nancy a patient with luxation of the sacrum. He had been caught under a freight elevator carrying two mineral cars weighing upward of two tons. He was pinned face downward, and was only released after twenty minutes. He was then comatose and cyanosed in the face, neck, and thorax. The pulse was small and threadlike. The patient was given injections of caffeine and etherized. The small quantity of urine obtained was clear at first, but slightly bloody at the end. The following day consciousness was more or less restored. The pulse was 120. Auscultation showed sibilant rhonchi disseminated through the chest. Some days later hematuria ensued, but this was not repeated. Five days later still, decided amelioration was manifest, but there were persistent pains in the sitting posture. Examination of the dorso-lumbar region showed a large ecchymosis and a deformity which, on the patient's lying down, conferred a saddle shape on the lumbar region. In the sitting posture a dorsal scoliosis and a lumbo-sacral lordosis became manifest. Pain was experienced in the recumbent position. A week later the patient could raise himself and began to walk

with difficulty with the aid of two sticks. The cyanosis of the face and thorax, the dorso-lumbar ecchymosis, the dorsal scoliosis, and the lumbo-sacral lordosis persisted. The patient lying down, the sacrum seemed to project from behind forward as though sunk in between the two iliac bones, which formed posteriorly an abnormal angle.

The patient's gait resembled that of a person with dislocation of both hip joints. His height, moreover, was diminished since the accident by six centimetres (about two inches and a quarter). There was no paralysis of the lower limbs, but the reflexes were exaggerated. The diagnosis made was that of a forward dislocation of the sacrum, which is very rare, only a few cases having been recorded, three of them by Malgaigne.

Supra-arterial Epicardial Fibroid Nodules.—In the March number of the *Journal of Experimental Medicine* there is an excellent article on this subject, by Dr. J. H. Mason Knox, Jr., of the pathological laboratory of the Johns Hopkins University and Hospital, based on a histological study of five well-marked examples found in making autopsies during the last few months.

These supra-arterial nodules, says Dr. Knox, differ from the ordinary tendinous or milky patches often observed upon the epicardium, especially over the right ventricle, in their multiplicity, their smaller size, and their distribution over the coronary arteries, to which they evidently bear some definite relationship. In gross appearance they resemble much more closely the nodular affection of the arteries first described by Kussmaul and Maier in 1866 under the name "periarteritis nodosa." This resemblance, however, is only superficial and does not pertain to the histological structure.

The author briefly reviews accounts of cases observed by Kussmaul and Maier, Chvostek and Weichselbaum, Heubner, Meyer, Fletcher, and von Kahlén. From this brief review the author remarks that there are several reported instances of an affection of the smaller arteries, characterized macroscopically by circumscribed whitish nodules distributed pretty generally through the body, except in the central nervous system, and microscopically by hypertrophy of both internal (except in the case of Kussmaul and Maier) and adventitial coats, with weakening and, in places, with rupture of the elastic coat. There was sometimes dilatation of the vessel, but usually the lumen was narrowed. The lesions in these cases were accompanied by clinical symptoms having much in common. The onset was sudden and marked by muscular pain, weakness, intermittent fever, and gastro-intestinal disturbances. There were occasionally also subsequent paralysis, anaemia, and nephritis. The course of the disease was progressively fatal, death resulting in all cases in from seven to twelve weeks.

Three suggestions have been made as to the etiology. Chvostek and Weichselbaum, reasoning from the close resemblance to arterial changes of known syphilitic origin, consider lues to be the cause of the lesions. Meyer and Eppinger think that the primary change is a weakening of the elastic membrane, while Fletcher and von Kahlén are of the opinion that the proliferation of the intima is the first step, and that this is brought about by the direct action of bacteria or of toxins.

The gross appearance of the nodules on the surface of the hearts in Dr. Knox's cases agrees closely, he says, with that of the arterial thickenings scattered generally through the body in the cases of so-called periarteritis nodosa. It is shown in Fig. 1.

FIG. 1

The appearances observed under the microscope differed somewhat in different cases, although the main lesion was constant. In four cases the following conditions were observed in cross sections including the coronary arteries with the nodules upon their adventitial surfaces: The intima of the arteries in the majority of sections examined showed little alteration. In several specimens there could be made out a marked increase in the intimal layer, either as a single mass bulging into the lumen, representing perhaps an organized mural thrombus, or as several smaller, more diffuse protrusions consisting of fusiform and branched cells with some intercellular substance. In the last case examined the intimal changes were much more pronounced, being most marked in situations corresponding to the nodes. The

hyaline metamorphosis were apparent. The changes in the adventitia proper were slight and inconstant. Only occasionally was there any hypertrophy.

The nodular formations lay upon the vessels within the epicardium, being seated primarily in the layer of connective tissue between the endothelial covering and the delicate layer of elastic fibres which rests upon the main layer of loose vascular connective tissue containing the epicardial fat. Their situation corresponded, therefore, to that of milky patches as determined by Ribbert.* In their immediate neighborhood were found the usual loose adipose and connective tissues, vessels, and nerves. But the nodules differed from the normal connective tissue, being at once distinguished from this by their dense and fibrous, often sclerotic, appearance.

The appearance on cross section was as though a compact mass of firm connective tissue, convex on its inner surface, were set upon the artery in the loose epicardial tissue. The lateral edges of the thickening slanted gradually upward to the surface and were continuous there with the epicardium. Scattered through the firm mass are a few fusiform connective-tissue cells. At the base of the area and at the sides there were often groups of lymphocytes and sometimes a small number of polymorphonuclear leucocytes (Figs. 2 and 4). The firm tissue had pushed up beyond the level of the rest of the epicardium and formed the opaque nodule seen in the gross specimen. The endothelium and occasionally some subjacent tissue covered the prominence and were continuous with the serosa over the rest of the heart. Beneath the nodules the layer of epicardial elastic tissue could usually be demonstrated, but the subjacent loose connective and adipose tissues were more or less atrophied.

The size of the fibrous thickening varied within wide limits, both in depth and in lateral extension. It might form a comparatively narrow band which was not raised above the surface of the epicardium; or, again, it might appear as a high, irregular, almost pediculated projection rising from a compact base above the vessel (Fig. 5).

The nodule might not only cover the outer surface of the vessel but might extend a considerable distance in the loose cellular tissue on each side (Figs. 4 and 5); or, on the other hand, there might be an oval patch over only a portion of an artery, the remaining circumadventitial covering being quite normal (Fig. 2).

The early stages of the process leading to the supra-arterial nodules presented a tissue richer in cells, both fibroblasts and lymphoid cells, situated superficially to the vessel and on its epicardial side. As the nodule became older, the more homogeneous and less cellular became its structure; the nuclei were fewer and the focus was more sharply differentiated from the surrounding tissue. In no instance was any tendency to a similar fibrous formation noticed on the side of the affected vessel next to the heart muscle, and no similar alterations

FIG. 2.—Transverse section of small artery in epicardium, surrounded by a fibroid nodule. The fibrous thickening is over about one half the width of the vessel. Hematoxylin and eosin staining. *A*, Intima. *B*, Inner elastic coat, wavy lines showing only at the sharper turns of the vessel wall. *C*, Media, slight swelling and degeneration (reduction in the number of nuclei beneath the nodule). *I*, Adventitial coat unaltered. *E*, Normal epicardium. *G*, Supra-arterial fibroid nodule projecting above the surface of the epicardium and extending to the adventitial membrane. *J*, Accumulation of small round cells in the epicardium at the sides of the node. *K*, Nerves in cross section. *L*, Capillaries. *M*, Portion of a vein evidently not associated with the fibrous nodule. *H*, Heart muscle.

entire internal coat was thickened, but the increase was especially marked in the myocardial hemispherical segment of the artery. In this situation it was of fully six times its normal thickness and the muscular tunica was somewhat diminished and degenerated. The increase in the thickness of the intima on the epicardial side was relatively slight, although the muscle in that region was degenerated and attenuated to a greater degree than on the opposite side of the vessel.

The muscular coat (media) was in the main, except in one instance, unchanged, so far as could be determined, in the sections stained by hematoxylin and eosin. Occasionally there was an apparent degeneration of muscular fibres as shown in a reduction in number of muscle cell nuclei, and there was exceptionally an infiltration with small round cells. In one case the media showed much more pronounced pathological changes, in that the tunica was reduced in thickness and areas of

* Virchow's *Archiv*, cxlvii, 1897, 211.

were seen about the arteries in the substance of the myocardium.

We have, then, in these cases, says Dr. Knox, nodules on the surface of the heart macroscopically resembling those described by Kussmaul and Maier, but totally dissimilar in their minute structure and relations: for the specimens stained in hæmatoxylin and eosin failed completely to show any constant degeneration or proliferation of the arterial walls, such as is present in periarteritis nodosa. The uniform relationship to arteries, however, suggested that there was probably some alteration in the vessel which was at least associated with the nodule. Hence a representative number of the sections were stained for elastic tissue by the fuchsin method of Manchot and by the method of Weigert.

The author gives the results of these stainings, and

Fig. 4. Specimen stained in fuchsin, Manchot's method. A, Intima. B, Inner elastic coat unaltered, no break or weakness beneath the nodule. C, Media. D, Outer elastic membrane between the media and the adventitial layer. This elastic membrane is thick and firm, and evidently supplying the chief support and giving the elasticity to the vessel wall. The membrane is intact, except at E, where beneath the nodule there is a marked fraying out and disappearance of the elastic fibres, with a consequent diminution in the strength of the arterial wall. E, F, G, H, I as in Fig. 2.

says that the microscopical observations indicate a relationship between the fibroid nodules and the demonstrated weakening in that part of the arterial wall immediately beneath the nodule.

In considering the ætiology of this certainly distinct lesion, says Dr. Knox, one must recall the disease, with which it may be associated. There was a distinct history of syphilis in one case; in three it was denied, with there is reason to be quite sure that there was no venereal infection in the fifth case. The nature of the histological changes does not correspond to that of a specific infection. The arterial alterations produced by the disease consist in an endarteritis associated usually with a periarteritis, or the direct inclusion of the vessel in a surrounding gummatous material. In the sections examined the arterial walls were unaffected, except in the nodules already described, and in no instance were any changes seen in the adjacent tissue.

So far as the gross appearances go, the nodules could

possibly be mistaken for tubercles. One of the subjects had suffered from a general tuberculous peritonitis for which laparotomy had been performed. In the other cases there was no evidence whatever, clinical or anatomical, of infection with the tubercle bacillus, and there was not the slightest sign of any tuberculous structure in any of the preparations.

Blood infection from either bacteria or their toxins was the cause suggested for periarteritis nodosa by Fletcher and von Kahlen. They based their hypothesis upon the primary proliferation of the intima which they attributed to the direct action of toxic substances in the circulation. This cellular increase in the intima was absent in most of the sections in Dr. Knox's cases, although it was present in one case. Moreover, cultures from the heart's blood were negative in two instances, while *Staphylococcus pyogenes albus* alone was found once, as was also in one case *Staphylococcus pyogenes aureus*. In the fifth case blood cultures taken during life remained sterile. It would be quite impossible to imagine that the nodules could be due to poisonous agents carried in the blood stream and producing this fibrous thickening on but one side of the artery, while they so rarely affect a vein and do not injure further the intermediate arterial coats. We may, therefore, doubtless exclude syphilis, tuberculosis, and other infections as essential ætiological factors in the production of these supra-arterial nodules.

The evidence seems to the author strongly to support the view that the primary, underlying cause is to be found in a weakening of the arterial wall, due usually to defects in one or both of the principal elastic lamellæ of the artery, most frequently of the elastica externa. All the cases were in men between nineteen and fifty-four years of age, accustomed, with one exception, to hard work, irregular methods of life, indifferent nourishment, and various quantities of alcoholic beverages. The heart was hypertrophied in four cases; in one there were valvular lesions, in two there was arteriosclerosis, in four there was nephritis, in four there was oedema, and in a single case aneurysm existed. These conditions indicate that during life there must have been irregularities in the force of the blood pressure, influenced further, doubtless, by the ingestion of large quantities of food. The duration of the final illness varied from eight weeks to two years. So far as known, no symptoms are attributable to the epicardial nodules.

As a probable explanation, then, of the origin of these fibroid nodules it is suggested that there is a weakening of the arterial coats, mainly of the outer elastic coat, on the side toward the nodule. While this defect may be congenital, it is more probable that it is acquired through poor nutrition combined with sudden alterations in blood pressure from the causes already indicated. This loss of elasticity, it may be supposed, is compensated for by a fibroid proliferation situated not in the vessel wall, but beyond it in the connective tissue.

For such an explanation an example is to be found in the views now generally held of the formation of aneurysms, first advanced by Rokitansky and later supported, with certain minor exceptions, by Fournier, P. Meyer, Manchot, Thoma, and others. The authorities consider the primary change to be a narrowing of the media, especially of the inner elastic coat and fibres, with subsequent bulging out of the vessel wall. When the weakening takes place in the outer elastic coat, the danger occurs in the intima and the danger of the danger of aneurysm is lessened by the narrowing of the arterial

FIG. 4.—Same specimen as in Fig. 3, stained by hematoxylin and eosin. A, Intima, with areas of proliferation probably not associated with the fibrous nodule. B, Inner elastic coat. C, Media apparently unchanged. D, Adventitial coat unaltered. E, Normal epicardium. F, Fibroid nodule projecting but slightly above the surface of the epicardium and extending to the adventitial coat beneath. G, Groups of small round cells at the side and beneath fibrous nodule. wall. Tears in the elastic lamellae are not uncommon, and may occur without the formation of aneurysm. The high pressure in the coronary arteries would seem to render these vessels particularly exposed to such injuries when the nutrition of their walls is impaired. Of special interest in the author's cases is the demonstration of more frequent and pronounced defects in the outer elastic lamella than in the internal one.

In no case was there an increase in the surrounding connective tissue corresponding to the inner, or myocardial, side of the artery, and it is to be conjectured that here the heart muscle affords sufficient support to prevent stretching of the vessel wall with such ruptures of the elastic lamellae as were observed on this side. Each pulsation must produce expansion of the artery, which is most marked at the point of least resistance, i.e., at the outer, or epicardial, surface. Excessive or irregular expansion can easily be thought of as injuring

more or less the elastic coat. In such cases there follows a still greater protrusion outward of the vessel wall with each pulsation. The significant localization of the defects in the outer elastic lamellae upon the epicardial side of the arteries indicates the greater exposure of the artery upon this side to injury, and this may be due to the lack of the support which is afforded to the myocardial side of the artery by the surrounding tissues. The firm resistance offered to the expansion of the vessel on the inner side by the ventricular wall is an important factor in favoring increased bulging in the free semicircumference. The absence of this counter-support probably accounts for the fact that similar nodules are rare upon the auricles.

Dr. Knox's conclusions are as follows:

1. Fibroid nodules seated in the epicardium directly over branches of the coronary arteries of the heart are not uncommon. They may be present in large numbers and are found most frequently upon the surface of the ventricles, but may occur over the auricles and even on the outer surface of the ascending aorta. They are rarely observed over the coronary veins.

2. While often resembling in gross and superficial appearances the nodules described by various writers under the name of "periarteritis nodosa," they differ from these in essential respects. They are seated outside of the adventitial coat and lie within the epicardium. They are composed of dense, fibrous, sclerotic tissue, poor in cells. In earlier stages of their formation they are richer in cells, both fibroblasts and lymphoid cells.

FIG. 5.—Transverse section of larger artery surmounted by a pronounced fibrous thickening, somewhat pedunculated and projecting abruptly from the surface. Same staining as in Fig. 3. A, Intima. B, Inner elastic coat, very thin, unaltered. C, Media. D, Outer elastic coat, compact only for a small portion of the circumference on the myocardial side. From this point on each side the fibres may be seen to separate into a network and to become diminished in number until at I they can not be demonstrated.

3. These supra-arterial nodules bear no definite relation to endarteritis, although they may be associated with this condition.

4. There were found with great regularity in the arterial wall immediately beneath the nodule, changes, which indicated a weakening of the wall in this situation. In some instances the muscular coat was thinned and degenerated, but the most common and important change was reduction and often disappearance of the elastic lamellæ and fibres, the outer elastic lamella being the one most frequently and intensely affected. These lesions were often limited to the segment of the arterial wall adjacent to the epicardium, the inner or myocardial segment of the same artery being free from similar alterations, or presenting them only in a slight degree. It is suggested that the absence on the outer or epicardial segment of the firm support afforded to the artery on the inner or myocardial aspect by the surrounding tissues renders the former more liable to damage to the elastic tissue resulting from irregularities and increase of blood pressure associated perhaps with defects of nutrition.

5. In consequence of the weakening in the arterial wall the artery would tend to bulge at the affected spot toward the epicardium were this tendency not restrained. The formation of the dense supra-arterial nodule of fibrous tissue over the weakened area holds this tendency in check, and may therefore be regarded as an adaptive or compensatory change.

The question as to the immediate exciting cause of the new growth of tissue offers the same difficulties as that pertaining in general to similar growths of connective tissue. Some would doubtless attribute it to direct stimulation from the pressure and shock of the impinging artery, others to defects in the tissue, and still others to a disturbance of the neighborhood relations of the part. It is not deemed necessary to enter into a discussion of these various hypotheses.

Dr. Knox concludes with brief histories of the cases in which his observations were made. We are indebted to him for permission to publish this abstract of his article and to the *Journal of Experimental Medicine* for the loan of the electrotypes of the illustrations.

Splenic Extract in Insanity.—According to the *Alienist and Neurologist* for April, Dr. Kerr and Dr. Bois, of Harwood, England, at the last meeting of the British Medical Association, reported twenty-two cases of insanity treated with splenic extract. Recovery occurred in eight and physical improvement in seventeen. The most tractable cases were those of stuporous insanity during adolescence.

Insanity Defined on the Basis of Disease.—Dr. C. H. Hughes (*Alienist and Neurologist*, April), in a paper presented to the *American Medical Psychological Association*, says that since modern research, assisted by the microscope, the test tube, and the crucible, has proved to us that there can be no expression of mental derangement unless there is a substratum of cortex disease, either in the neurone, in the enveloping membranes of the brain, in the nourishing blood supply, in the behavior of the vasomotor mechanism, or remotely in any of the organs of the body affecting the brain, we are to cause these conditions, we need never be at sea before any court or any jurist in defining insanity as a disease, one primarily or secondarily involving the brain, of the individual so as to produce in him a change in the natural habits of thought, feeling, or action. A change of

his normal, natural mental expression by which, and by reason of the disease underlying all, he is placed out of harmony with his surroundings, with his natural self, or with his normal family type of mind."

A Death following a Sty.—H. Guth (*Progr. medizinische Wochenschrift*, No. 3, 1898; *St. Paul Medical Journal*, May, 1899) says that a woman was brought into the clinic with both lids greatly swollen, the conjunctiva chemotic, both eyeballs protruding, high fever, Cheyne-Stokes breathing, tonic and clonic spasms. Ophthalmoscopic examination showed septic retinitis; death followed; post-mortem showed that there was suppurative meningitis which had proceeded through infection from a hordeolum; the suppuration had infiltrated the orbital tissues and penetrated through the right cavernous sinus to the meninges.

Book Notices.

Die gestielten Anhängel des Ligamentum Latum. Von Dozent Dr. EMIL ROSSA, in Graz. Mit zwei lithogr. Tafeln. Berlin: S. Karger, 1899. Pp. 51.

THE author, finding the subject of the pedunculated cysts of the broad ligament but little understood, has endeavored to clear up their origin and nature. This he has been able to do only partially. Some arise from remnants of the paroophoron, others from cystic degeneration of the fimbriae of the tube, others from remnants of the fallopian canal between the abdominal cavity and the primitive kidneys. A complete review of the literature of the subject is given.

La Pulsation du pied. Essai sur un nouveau signe clinique. Par le Docteur SILVIO TARRI, Directeur du laboratoire de l'hôpital Rivadavia, etc. Buenos Aires: J. Pensier, 1898. Pp. 3 to 44.

IT is a well-known fact that when the lower limbs are crossed there is a vibration of the upper, free limb exactly synchronous with the cardiac pulsation. This vibration the author thinks is due, not to the amplification of the beat of the popliteal artery, but to the systole and diastole of the smaller arterioles and the capillaries of the limb. He finds certain differences in the form of the curves from those obtained at the radial of the same patient, and maintains that an early diagnosis of arteriosclerosis can be made from the tracing. To the casual observer the curves obtained differ in no way from those from the radial artery in the same case, except that the great weight and momentum of the leg acting as a lever prevent the registration of the finer shades of the vascular pressure obtainable by the use of a very light and short lever, such as is used in the ordinary sphygmograph.

Notes on Surgery for Nurses. By JOSEPH B. HILL, M.D., F.R.C.S. Edin., Consultant Surgeon to the Royal Infirmary and to the Royal Edinburgh Hospital for Sick Children. Fifth Edition, thoroughly revised. Edinburgh: Oliver & Boyd, London: Simpkin, Marshall, Hamilton, Keir & Co., 1899. Pp. 9 to 194. [Price, 2s. 6d.]

THE fifth edition of this very excellent little volume on surgical nursing has been thoroughly revised and

brought up to date. A new and useful appendix has been added on the relation of the nurse to the profession and the public which can not help being of value to those for whom it is intended.

Golden Rules of Surgical Practice. By E. HURRY FENWICK, F. R. C. S., Surgeon to and Lecturer on Clinical Surgery at the London Hospital, etc. Golden Rules Series. No. 1. Fifth Edition, revised and enlarged. London: Simpkin, Marshall, Hamilton, Kent, & Co., 1899. Pp. vi-10 to 71. [Price, 1s.]

THE writing of this little guide was suggested by an observation made by the author concerning the vast learning displayed by his surgical internes in all questions of recent theories of disease and their equally vast ignorance of the little, practical, everyday facts so necessary in the care of patients. For the purpose of instructing beginners in the practical rudiments of surgery this volume will prove excellent.

Golden Rules of Obstetric Practice. By W. E. FOTHERGILL, M. A., B. Sc., M. D., Author of *A Manual of Midwifery*, etc. Golden Rules Series. No. 3. London: Simpkin, Marshall, Hamilton, Kent, & Co., 1899. Pp. 4 to 71. [Price, 1s.]

AN excellent collection of short sensible rules to be observed during attendance in a case of obstetrics.

Golden Rules of Gynecology. By S. JERVOIS AARONS, M. D., Registrar to the Hospital for Women, etc. Golden Rules Series. No. 2. London: Simpkin, Marshall, Hamilton, Kent, & Co., 1899. Pp. 11 to 63. [Price, 1s.]

THE medical student will find many useful hints on practical gynecology in this small volume.

BOOKS, ETC., RECEIVED.

The Diseases of the Nervous System. A Text-book for Physicians and Students. By Dr. Ludwig Hirt, Professor at the University of Breslau. Translated, with Permission of the Author, by August Hoch, M. D., formerly Assistant Physician to the Johns Hopkins Hospital, etc., assisted by Frank R. Smith, A. M. (Cantab.), M. D., Instructor in Medicine in the Johns Hopkins University. With an Introduction by William Osler, M. D., F. R. C. P., F. R. S., Professor of Medicine in the Johns Hopkins University, etc. With One Hundred and Eighty-one Illustrations. New York: D. Appleton and Company, 1899. Pp. xvi-715. [Price, \$5.]

Treatise on Human Physiology. For the Use of Students and Practitioners of Medicine. By Henry C. Chapman, M. D., Professor of Institutes of Medicine and Medical Jurisprudence in Jefferson Medical College, Philadelphia, etc. Second Edition. Illustrated with Five Hundred and Ninety-five Engravings. Philadelphia: Lea Brothers & Co., 1899. Pp. 9 to 924. [Price, \$4.25.]

Laboratory Work in Bacteriology. By Frederick G. Noy, Sc. D., M. D., Junior Professor of Hygiene and Physiological Chemistry, University of Michigan. Second Edition, revised and enlarged, with Frontispiece and Seventy-six Illustrations. Ann Arbor, Michigan: George Wahr, 1899. Pp. 3 to 563.

Pericardial Diseases, Illustrated Clinically. By Thomas E. Satterthwaite, M. D. [Reprinted from the *Medical Times*.]

The Shape and Position of the Stomach. By Henry Wald Bettman, M. D., of Cincinnati. [Reprinted from the *Philadelphia Monthly Medical Journal*.]

Cupulence and the Fatty Heart. By Thomas E. Satterthwaite, M. D. [Reprinted from the *Post-graduate*.]

Miscellany.

The Lenval Prize.—This prize, which has been founded by Baron Léon de Lenval, of Nice, will be awarded at the International Otological Congress to be held in London, from August 8 to 11, 1899. The regulations for its award, which were passed at the Fifth International Otological Congress, held in Florence in 1895, are as follows—viz.: 1. In connection with the International Congresses of Otolgy, the sum of three thousand francs has been given to found a prize, bearing the name of "the Lenval prize." 2. The interest of this sum, which has accumulated between one International Otological Congress and the next, shall be awarded to the author of the most marked progress bearing on the practical treatment of affections of hearing during that time or to the inventor of any new apparatus which is readily portable and improves considerably the hearing power of deaf persons. 3. The sum of three thousand francs will be deposited in a public bank in the hands of the president of the jury. 4. The International Otological Congress will elect a jury each time, consisting of seven members. The jury will pronounce its decision at the closing meeting of each congress. The members of the jury, as at present constituted, are Professor Politzer (Vienna), Dr. Benni (Warsaw), Dr. Gellé (Paris), Professor Pritchard (London), Professor St. John Roosa (New York), Professor Kirchner (Würzburg), and Professor Grazi (Florence). All persons desirous of competing for the prize are requested to communicate without delay with Mr. E. Cresswell Baber, honorary secretary-general, 46 Brunswick Square, Brighton, England, stating the facts on which their claim is based.

Cancer Hospitals in New York.—Apropos of a recent newspaper discussion, the following declaration of policy has been issued by the New York Skin and Cancer Hospital:

"Whereas, Public appeals are being made for funds to establish and support a 'Home for Cancer Incurables,' and some of these appeals are in substance and form such as possibly to create a wrong impression regarding the purposes and works of our own institution; and

"Whereas, It is expedient that we should leave no uncertainty in the public mind regarding our work and the tests by which alone it may fairly be judged; now, therefore, it is

"Resolved, That we, the board of governors of the New York Skin and Cancer Hospital, in regular meeting, adopt the following propositions as a minute declaration of the institution's policy in regard to so-called incurable cases of cancer:

"We are a free hospital for cancer, as well as for skin diseases. Admittance to clinics or general wards is in no case conditioned solely on ability to pay. Nor is a patient ever discharged for mere inability to pay.

The only payment that is ever requested is a small sum for board. A ward patient who pays a dollar a day is officially reported as 'full pay.' Only a small proportion of our patients has at any time belonged to this class. The management has in mind its obvious duty to its patrons, its beneficiaries, the medical profession, and society at large in pursuing this course. By far the greater part of our patients pay little or nothing, and the board recognizes that this must continue to be true.

"We are a hospital, and, as such, exist primarily to afford facilities for the scientific treatment of specific diseases, and only secondarily (if at all) to receive sufferers who require tender care but are presumably or demonstrably not susceptible of cure or betterment.

"Throughout our history we have recognized that it is a part of our privilege and duty to pursue the scientific study of cancer with a view to removing the present dead-line of incurability. It is therefore neither our policy nor our practice to reject all inoperable cases—in fact, we have nearly always had some such among our absolutely free patients.

"We maintain a staff of recognized specialists in medicine and surgery, who are wholly unpaid. If we permitted the hospital to become a mere home for incurables, we could not retain the services of these physicians. Their presence would not be needed and their observations would not benefit science or society. So long, therefore, as our endowment and contributions are inadequate to maintain the much-needed and acknowledgedly more valuable hospital service, we must continue to limit our ward service primarily to curable and improvable cases.

"We recognize the need of some proper charitable accommodation for indigent sufferers who are beyond hospital treatment. We would welcome the wise establishment of such an institution on a thoroughly liberal basis. For years we have been appealing generally for money in behalf of cancer sufferers. Friends have to some extent come forward to perfect and enlarge our hospital plant; and we are still laboring at this, which we regard as our first duty. We have not yet been placed in a financial position justifying our undertaking the supplemental work of exclusively incurable wards. If charitable people wish to intrust this particular work to others we do not complain. We only remind them that no amount or kind of provision for incurables can remove or even diminish the pressing necessity for strictly hospital facilities. Indeed, the very fact of the demand for a home is the best proof of the need for larger and better hospital service to check if possible the increasing ravages of the disease.

[Signed.]

"FLETON McMAHON,

"J. E. JANVIER, M. D.,

"Committee.

"New York, April 11, 1899.

The Medical Society of the State of North Carolina will hold its forty-sixth annual meeting in Asheville, Tuesday, Wednesday, Thursday, and Friday, May 30th and 31st and June 1st and 2d, under the presidency of Dr. L. J. Pratt, of Lattimore. Inquiries concerning matters pertaining to local arrangements should be addressed to Dr. M. H. Fletcher, Asheville.

The First Meeting of Rectal Specialists is to be held in Columbus on Tuesday, Wednesday, Thursday and Friday, June 6th, 7th, 8th, and 9th. The program is as follows: The Importance of giving Rectal Disease Special Study, by Dr. Joseph M. Mathews, of Louisville;

Pruritus Ani, by Dr. James P. Tuttle, of New York; The Surgical Treatment of Non-malignant Stricture of the Rectum, by Dr. Joseph B. Bacon, of Chicago; A Modification of Whitehead's Operation for Hemorrhoids, by Dr. Samuel T. Earle, Jr., of Baltimore; The Proctoscope as a Factor in the Diagnosis and Treatment of Simple Ulceration of the Rectum, by Dr. Leon Straus, of St. Louis; A Consideration of the Various Forms of Ulceration of the Rectum, by Dr. Lewis H. Adler, Jr., of Philadelphia; Rectal Carcinoma—Excision and Subsequent Colotomy, by Dr. B. Merrill Ricketts, of Cincinnati; The Limitations of the Kraske Operation, by Dr. Charles C. Allison, of Omaha; The Act of Defecation, by Dr. Thomas Charles Martin, of Cleveland; Constipation considered from the Standpoint of the Proctologist, by Dr. A. Bennett Cooke, of Nashville; a paper and exhibition of new instruments, by Dr. S. G. Gant, of Kansas City; and Rectal Adenomata, by Dr. William M. Beach, of Pittsburgh.

The Late Dr. Hunter.—The *Lancet* for April 22d contains a letter from Major Greenwood, M. D. Brunsell, LL.B. London, barrister at law, with reference to Dr. Hunter, who was prosecuted some time back for styling himself "physician," when his only English diploma was the license of the Society of Apothecaries. Dr. Hunter, it appears, held the M. D. degree from Jefferson College, Philadelphia, the authenticity of which was verified by Dr. Greenwood by communication with the dean of that institution. Dr. Greenwood, who represents, we think, fully the accord of the English medical profession on that subject, says that the fact that a registered medical practitioner with such a degree should be refused the honorary title of "M. D." in England seems to him monstrous, and he thinks that his opinion would be shared by any medical graduate of an English university who, being resident in Philadelphia after acquiring the State license to practise there, was similarly refused the same honorary distinction. The holder of an M. D. degree of any recognized university, he says, unless that university withdraws the distinction, must continue to be a doctor of medicine independently of all political considerations, wherever he resides. This has nothing whatever to do with the right to practise medicine, which is quite another matter.

The New York Hospital Report. The report for the year 1898, recently issued, deals rather more largely with matters pertaining to the history of the hospital than has usually been the case. In particular, there is an interesting history of the library, by Dr. A. Brayton Ball. It is embellished with portraits of Dr. Samuel Bard, Dr. John Jones, Dr. Richard Bayley, Dr. James Tillary, Dr. Wright Post, Dr. J. R. B. Rodgers, Dr. Samuel Borrowe, Dr. Valentine Seaman, Dr. Elum H. Smith, Dr. Samuel L. Mitchell, Dr. David Hosack, Dr. William Humesley, Dr. Edward Miller, Dr. Archibald Bruce, Dr. Valentine Mott, Dr. Alexander H. Stevens, Dr. John Watts, Dr. John Nelson, Dr. Thomas Cock, Dr. John C. Chesman, Dr. J. Kearney Rogers, Dr. Samuel W. Moore, Dr. Stephen Brown, Dr. Francis F. Johnston, Dr. James Macdonald, Dr. Joseph M. Smith, Dr. Guy C. Bayly, Dr. John B. Beck, Dr. Edward Delafield, Dr. Alfred C. Post, Dr. John G. Adams, Dr. Gordon Rock, Dr. Benjamin Ogden, Dr. William Wilson, Dr. John W. W., Dr. John A. Swett, Dr. John H. Griscom, Dr. P. H. Park, Dr. Henry D. Bulkley, Dr. Charles H. Nelson, Dr. Ebeneser M. Hallsted, Dr. Thomas M. Marks, Dr. D. Tilden Brown, Dr.

William H. Van Buren, Dr. John T. Metcalf, Dr. Thomas F. Cock, Dr. Willard Parker, Dr. George A. Peters, Dr. Thomas B. Dash, Dr. William H. Draper, Dr. Henry B. Sands, Dr. Charles M. Allin, Dr. Gouverneur M. Smith, Dr. Charles E. Hackley, Dr. James W. McLane, Dr. Ernst Kracowizer, Dr. Woolsey Johnson, Dr. Edward L. Partridge, and Dr. W. Gilman Thompson, who served as medical officers in the past, and Dr. Robert F. Weir, Dr. William T. Bull, Dr. George L. Peabody, Dr. A. Brayton Ball, Dr. Lewis A. Stimson, Dr. Samuel B. Lyon, Dr. Frank Hartley, Dr. Francis W. Murray, Dr. Henry P. Loomis, Dr. Samuel W. Lambert, and Dr. Lewis A. Conner, who are still in the service of the institution.

The Journey to Columbus.—The committee on transportation of the New York County Medical Association is arranging for rates, train service, etc., for the Columbus meeting of the American Medical Association, to be held on June 6th, 7th, 8th, and 9th. Those intending to go, and desiring to take advantage of such arrangements as may be made, will kindly address, as soon as possible, Dr. Parker Syms, chairman of the committee, No. 50 West Forty-seventh Street.

The Determination of the Placental Site by Palpation.—Dr. C. F. Close, of Chicago, has sent us an account of the method of ascertaining the situation of the placenta taught and practised by Professor Leopold, of Dresden. In nearly all cases, says Dr. Close, the Fallopian tubes are palpable. If they converge from above downward or are parallel, the placenta is seated anteriorly; if they diverge from above downward, the situation of the placenta is posterior. This is of special importance, Dr. Close remarks, when the question of inducing premature labor by introducing a bougie between the fetal membranes and the uterine wall or that of performing the Cesarean operation arises, in order to avoid the placental site. Dr. Close gives the statistics of placental implantation as follows: Posteriorly, fifty per cent.; anteriorly, forty per cent.; to the right, six per cent.; to the left, four per cent.

The Revision of the Pharmacopœia.—Dr. H. C. Wood, of Philadelphia, has issued the following proclamation, dated May 1st:

"To all whom it may concern: In accordance with instructions given by resolutions passed at the National Convention for Revision of the Pharmacopœia of the United States of America, held in Washington, A. D. 1890, I herewith give notice that a General Convention for the Revision of the Pharmacopœia of the United States of America will be held in the city of Washington, D. C., beginning on the first Wednesday in May, 1900. It is requested that the several bodies represented in the conventions of 1889 and 1890, and also such other incorporated State medical and pharmaceutical associations and incorporated colleges of medicine and pharmacy as shall have been in continuous operation for at least five years immediately preceding this notice, shall each elect delegates, not exceeding three in number; and that the surgeon-general of the army, the surgeon-general of the navy, and the surgeon-general of the Marine-Hospital Service shall appoint, each, not exceeding three medical officers to attend the aforesaid convention.

"It is desired that the several medical and pharmaceutical bodies and the medical departments of the army, navy, and Marine-Hospital Service shall transmit to me the names and residences of their respective delegates,

so soon as said delegates shall have been appointed, so that a list of the delegates to the convention may be published in accordance with the resolutions passed at the 1890 convention for the revision of the Pharmacopœia, in the newspapers and medical journals in the month of March, 1900.

"Finally, it is further requested that the several medical and pharmaceutical bodies concerned, as well as the medical departments of the army, navy, and Marine-Hospital Service, shall submit the present pharmacopœia to a careful revision, and that their delegates shall transmit the result of their labors to Dr. Frederick A. Castle, 51 West Fifty-eighth Street, New York city, secretary of the committee of revision and publication of the United States Pharmacopœia, at least three months before May 2, 1900, the date fixed for the meeting of the convention."

The American Laryngological Association will hold its twentieth annual meeting in Chicago on Monday, Tuesday, and Wednesday, May 22d, 23d, and 24th, under the presidency of Dr. W. E. Casselberry, of Chicago. Physicians who are interested in laryngology are invited to attend.

The Nebraska State Medical Society held its thirty-first annual meeting in Lincoln on Tuesday, Wednesday, and Thursday, May 9th, 10th, and 11th, under the presidency of Dr. A. R. Mitchell, of Lincoln. After a general meeting for matters of business, the professional proceedings were conducted in sections as follows: Laryngology, Dr. S. E. Cook, of Lincoln, chairman; Nervous and Mental Diseases, Dr. J. L. Greene, of University Place, chairman; Public Hygiene and Medical Legislation, Dr. C. C. Gafford, of Wymore, chairman; Practice of Medicine, Dr. Claude Watson, of Nebraska City, chairman; Surgery, Dr. Byron B. Davis, of Omaha, chairman; Ophthalmology and Otology, Dr. D. C. Bryant, of Omaha, chairman; Anatomy and Physiology, Dr. J. B. Hlungate, of Weeping Water, chairman; Obstetrics and Gynecology, Dr. Robert McConaughy, of York, chairman; Materia Medica and Therapeutics, Dr. F. W. Lester, of David City, chairman; and Histology and Pathology, Dr. W. R. Lavendar, of Omaha, chairman.

Congenital Extrusion of the Stomach.—At the recent meeting of the South Carolina State Medical Association Dr. D. M. Crosson, of Leesville, presented a fetus, which he judged to be of about six months' development, showing an aperture in the upper part of the abdominal wall through which the stomach protruded. In addition, there was no anus. The child had breathed for a few moments after its birth.

Anomalous Ducts of Exit from the Parotid Gland.—At the same meeting Dr. Crosson reported the cases of four out of a family of seven children who had congenital openings in front of the external ear from which a constant discharge issued. In three of the children the opening existed in front of each ear, and in the fourth it was on the left side only. Dr. Crosson had satisfied himself by probing and other methods of examination that these anomalous passages were ducts leading from the parotid gland. When these ducts became obstructed, as they occasionally did, suppuration followed. Two of these children's cousins, children of the mother's brother, also had like malformations, so that six cases in all were reported.

Original Communications.

THE SIGNIFICANCE OF ABSENCE OF NUCLEATED RED CORPUSCLES IN THE BLOOD IN CASES OF GRAVE ANÆMIA.

By JOHN S. BILLINGS, JR., M. D.,

ASSISTANT BACTERIOLOGIST, DEPARTMENT OF HEALTH, NEW YORK CITY;
INSTRUCTOR IN CLINICAL MICROSCOPY
IN NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL SCHOOL.

IN attempting to form a prognosis in cases of grave anæmia several things must be taken into consideration. Such anæmias are, as a rule, secondary to severe or persistent hæmorrhage from various causes, or to malnutrition, such as occurs in cases of complete atrophy of the gastric mucous membrane, carcinoma of the stomach, etc. It is probable that in time the term primary pernicious anæmia will be limited to an extremely small group of cases for which no cause other than alterations in the blood-making organs (marrow, spleen, etc.) can be found. At the present day, however, many cases of progressive and fatal anæmia do occur for which no primary cause can be assigned, and in which the steadily increasing destruction of the red corpuscles is supposed by most authorities to be due to disease of the blood-making organs or to some agency originating within the circulating blood itself.

In extra-uterine life the red corpuscles are probably formed in the marrow of the bones. This is in health their only source, but in disease the spleen is supposed to again take up the making of red corpuscles—a function it normally loses at or before birth. But under all circumstances, the large majority of the red corpuscles are formed in the marrow. Certain nucleated marrow cells, called for convenience “mother cells,” divide and produce other nucleated cells which take up or form hæmoglobin, extrude their nuclei, and pass into the circulating blood as normal red corpuscles. In health the nucleus is always extruded while the future red corpuscle is still within the bone marrow. When abnormal destruction or loss of red corpuscles occurs in the blood, the formation of new corpuscles in the marrow is correspondingly increased. Where such destruction or loss is not too great, the marrow is equal to the task and keeps the blood supplied with normal non-nucleated red corpuscles. But when the destruction or loss is too great, the blood-making powers of the marrow become insufficient, and nucleated red corpuscles appear in the circulating blood. This signifies that the marrow is producing red corpuscles so rapidly that there is not sufficient time for all of them to extrude their nuclei while still within the marrow. The bone marrow in health contains considerable fat and is of a yellowish color. Where it is called upon to produce large numbers of red corpuscles, as in grave anæmia, the fat disap-

pears, the marrow becomes reddish, and is said to have reverted to the embryonic type. Microscopical examination in such cases shows greatly increased numbers of mother cells, daughter cells, nucleated red corpuscles, and ordinary red corpuscles. Another evidence of increased activity on the part of the marrow is the presence in the blood of the so-called polychromatophilic red corpuscles, which were first described by Gabritchewsky. These are red corpuscles, nucleated or non-nucleated, which exhibit a variation from the normal in staining reaction. The normal red corpuscle, when stained with the Ehrlich-Biondi triple stain, is of an orange color. In cases of severe anæmia certain corpuscles will be seen which stain violet instead of orange. As a rule, fully fifty per cent. of the nucleated red corpuscles are polychromatophilic, and the greater the number of nucleated corpuscles the more numerous are the non-nucleated polychromatophiles. This abnormal staining reaction was at first believed to be an evidence of degenerative change (necrobiosis; Ehrlich); but, as it is so frequently seen in nucleated red corpuscles, and as such corpuscles are undoubtedly immature, the consensus of opinion at present is that polychromatophilia is an evidence of increased new formation of red corpuscles. The whole process is an attempt at regeneration on the part of the blood-making organs, and the appearance of nucleated and polychromatophilic red corpuscles in the blood is an evidence of such a process. In cases of severe anæmia (1,500,000 red corpuscles or less to the cubic millimetre) careful examination of the blood will, in a great majority of the cases, show the presence of nucleated and polychromatophilic red corpuscles. Where recovery takes place, the number of red corpuscles increases, there is no longer any necessity for abnormal activity on the part of the marrow, and the nucleated and polychromatophilic red corpuscles gradually disappear from the blood. Where the cases terminate fatally, the marrow usually continues its blood-making activity until the end. In fact, the number of nucleated red corpuscles in the blood may steadily increase, while the total number of red corpuscles is steadily diminishing. The marrow continues its hopeless fight until the end, though steadily losing ground all the while.

Now it has been noted in a certain small number of cases that the bone marrow loses its power of forming red corpuscles comparatively early. In these cases the anæmia steadily increases, and the cases always terminate fatally. Such cases can be recognized by examination of the blood, as they show no evidence of any attempt at regeneration, i. e., no nucleated or polychromatophilic red corpuscles are to be found. Ehrlich has reported such a case in 1884. The patient had suffered from severe post-partum hæmorrhage and was very anæmic. A blood examination failed to show any nucleated red corpuscles, and the patient died within a week.

The following cases have been seen by the writer during the past five years:

CASE I. *Purpura Hæmorrhagica with Extreme Anæmia.*—Seen at the Johns Hopkins Hospital, Baltimore,* March 22, 1894. A. F., a boy, aged ten years. Complaining of pallor and subcutaneous hæmorrhages.

Family and past history negative.

Present illness began eight weeks previously with pallor, debility, and subcutaneous hæmorrhages. Slight hæmoptysis for the last two weeks. No melæna, hæmatemesis, or hæmaturia. No joint involvement.

Physical Examination.—Boy fairly well nourished; marked anæmia; ecchymoses over chest and legs; larger extravasations on shoulders and legs; loud systolic murmur heard over apex of heart. Examination of lungs and abdomen negative.

Urine showed a slight trace of albumin. No casts. Death took place suddenly on March 30, 1894.

Blood on admission: Red corpuscles, 696,000 to the cubic millimetre; leucocytes, 4,000 to the cubic millimetre; hæmoglobin, fifteen per cent.; hæmoglobin index, 1.07.

Stained specimens practically negative. No nucleated nor polychromatophilic red corpuscles seen in a large number of specimens. Little poikilocytosis (abnormalities in shape). Little schizocytosis (abnormalities in size). Daily examination of the blood showed a progressive diminution in the number of red corpuscles.

March 30th.—Blood: Red corpuscles, 483,000 to the cubic millimetre; leucocytes, 7,000 to the cubic millimetre; hæmoglobin, fifteen per cent.; hæmoglobin index, 1.5.

An unfavorable prognosis, based upon the severe anæmia and absence of any attempt at regeneration on the part of the blood-making organs, was given. This was confirmed by the death of the patient eight days later.

CASE II. *Purpura Hæmorrhagica with Severe Anæmia.*—Seen at Dispensary of St. Vincent's Hospital, New York city, August 15, 1895. P. D., a boy, aged a year and six months. Complaining of debility and subcutaneous hæmorrhages.

Family history and past history negative. Has always been rather delicate.

Present illness began five weeks previously with an eruption of subcutaneous hæmorrhages over the entire body. Child soon became pale and weak. Two weeks later he vomited about half a cupful of blackish coagulated blood, and for three days thereafter stools were tarry. Appetite remarkably good. No fever. No involvement of joints.

Physical Examination.—Fairly well-nourished child. Marked anæmia and a waxy look to the skin. Scattered subcutaneous ecchymoses over entire body, most numerous on legs. Several large extravasations on posterior aspect of legs, especially in popliteal spaces. Soft systolic murmur heard over apex of heart. No venous hum in neck. Examination of lungs and abdomen negative. Specimen of urine not obtained.

Blood: Red corpuscles, 1,300,000 to the cubic millimetre; leucocytes, 18,200 to the cubic millimetre; hæmoglobin, twenty-two per cent.; hæmoglobin index, 0.8.

Stained specimens showed moderate poikilocytosis of

red corpuscles. No nucleated nor polychromatophilic red corpuscles seen. A differential count of the leucocytes showed the moderate leucocytosis to be due to an increase in the so-called polynuclear forms. Multinuclears, 79.7 per cent.; lymphocytes, 9.3 per cent.; large uninuclears, 8.6 per cent.; eosinophiles, 2.4 per cent.

August 22, 1895.—No improvement. Pallor more marked. A few fresh subcutaneous hæmorrhages. Mother stated that diaper had been stained red four days previously.

Blood: Red corpuscles, 993,000 to the cubic millimetre; leucocytes, 3,200 to the cubic millimetre; hæmoglobin, eighteen per cent.; hæmoglobin index, 0.9.

Stained specimens as previously.

A very bad prognosis was given for the same reasons as in Case I. The case was not seen again, but upon inquiry it was learned that the child died August 31, 1895.

CASE III. *Progressive Fatal Anæmia following Childbirth.*—Case seen in consultation, February 15, 1897. E. M., a woman, aged thirty-three years; married. Complaining of great pallor and dyspnœa.

Family history negative.

Past History.—Patient had always been strong and healthy. No serious illness. Married three years. Menses regular; never profuse. No tendency to hæmophilia.

Present Illness.—Patient gave birth to a dead fœtus (her first pregnancy) six weeks previously. She had been under the care of another physician, so that details of the labor were not obtainable. Labor lasted about forty-eight hours, and death of child was supposed to be due to pressure on the umbilical cord. Twenty-four hours after the termination of labor the patient had a severe hæmorrhage. This was finally checked, but was followed by two more hæmorrhages during the next two days. A change of physicians was made, and the second attendant found the patient almost exsanguinated. A portion of the placenta had been retained and there were severe lacerations of the cervix and perinæum. She was given tonics and iron, but no benefit ensued, though she was able to leave her bed for a week. The anæmia and dyspnœa persisted and she was compelled to take to her bed again.

Physical Examination.—Fairly well-nourished woman. Very anæmic. Soft, blowing systolic murmur heard over entire cardiac area. Marked venous hum in cervical veins. Examination of lungs and abdomen negative. Urine is said to have contained 0.1 per cent. albumin. Pale. No casts.

Blood: Red corpuscles, 898,000 to the cubic millimetre; leucocytes, 26,000 to the cubic millimetre; hæmoglobin, twenty per cent.; hæmoglobin index, 1.1.

Stained specimens showed moderate poikilocytosis and schizocytosis. No nucleated nor polychromatophilic red corpuscles seen in twenty specimens. Leucocytosis due to an increase in the so-called lymphocytic elements; a lymphæmia. Multinuclears, 19.2 per cent.; lymphocytes, 68.6 per cent.; large uninuclears, twelve per cent.; eosinophiles, 0.2 per cent.

Prognosis most unfavorable. The patient died three days later.

CASE IV. *Pernicious Anæmia; Arthritis Deformans.*—Seen at dispensary of the Presbyterian Hospital, August 13, 1898. A. M., a woman, aged forty-seven years; single. Complaining of painful swelling of wrists, pallor, and oedema of ankles.

Family History.—Mother and maternal grand-

* This case was reported by the writer in the *Johns Hopkins Hospital Bulletin*, vol. v, 1894, p. 65.

mother both suffered from the same joint affection as the patient.

Past History.—Always healthy. Dyspeptic. Arthritis deformans limited to carpal and metacarpal joints for twelve years.

Present Illness.—Began eight months previously with debility, increasing pallor, and dyspnoea. Has lost weight. Urine, two per cent. albumin. Few hyaline casts.

Physical Examination.—Sparely nourished woman. Marked anaemia. Slight earthy jaundice. Soft systolic murmur heard over apex of heart. Faint venous hum heard over cervical vessels. Both kidneys palpable. Lungs clear. (Edema of ankles.)

Blood: Red corpuscles, 1,344,000 to the cubic millimetre; leucocytes, 9,200 to the cubic millimetre; haemoglobin, forty-eight per cent.; haemoglobin index, 1.8.

Stained specimens showed moderate poikilocytosis and schizocytosis. No nucleated nor polychromatophilic red corpuscles. Leucocytes. Marked increase in the lymphocytic forms. Lymphocytes, 84.3 per cent. Large mononuclears, 6.1 per cent.; polynuclears, 9.5 per cent.; eosinophiles, 0.1 per cent.

August 20, 1898.—No improvement.

Blood: Red corpuscles, 1,060,000 to the cubic millimetre; leucocytes, 18,300 to the cubic millimetre; haemoglobin, thirty-nine per cent.; haemoglobin index, 1.3.

Stained specimens as before, 94.3 per cent. lymphocytes.

Prognosis entered as most unfavorable. Patient died at her home two weeks later.

CASE V. Carcinoma of Uterus with Grave Anaemia.—Seen at Bellevue Hospital, January 30, 1899. M. C., a woman, aged thirty-five years; married. Complaining of weakness and abdominal pain.

Family history negative. Past history negative.

Present Illness.—Increasing pallor and dyspnoea for six months. Has had attacks of pain in lower part of abdomen for about a year. Menses irregular but not profuse. No intercurrent hemorrhages.

Physical Examination.—Fairly well-nourished woman. Marked anaemia. Slight waxy color of skin. Soft systolic murmur over apex of heart. Soft venous hum heard over cervical veins. Examination of lungs and abdomen negative. Examination by gynecologists revealed the presence of a tumor of the fundus of the uterus, in all probability cancerous. Urine examination negative.

Blood: Red corpuscles, 1,021,000 to the cubic millimetre; leucocytes, 19,200 to the cubic millimetre; haemoglobin, nineteen per cent.; haemoglobin index, 0.9.

Stained specimens showed no poikilocytosis nor schizocytosis. No nucleated red corpuscles. A few polychromatophilic red corpuscles. Leucocytosis due to an increase in the polynuclear forms. Multinuclears, 81.2 per cent.; lymphocytes, 12.1 per cent.; large mononuclears, 6.1 per cent.; eosinophiles, 0.4 per cent.

February 1st.—No improvement.

Blood: Red corpuscles, 992,000 to the cubic millimetre; leucocytes, 21,300 to the cubic millimetre; haemoglobin, eighteen per cent.; haemoglobin index, 0.9.

Stained specimens as before. No nucleated red corpuscles seen in fifteen specimens. Leucocytosis polynuclear.

Prognosis unfavorable. Patient died one week later.

REMARKS.—The cases reported above, while too few in number to warrant any definite conclusion, go to show

that the absence of nucleated red corpuscles in the blood in cases of grave anaemia indicates that there is no new formation of red corpuscles taking place, and that therefore the prognosis of such cases is extremely unfavorable. The writer has attempted to make a special study of diseases of the blood during the past seven years, and in that time has examined the blood in a large number of cases of severe anaemia. The cases reported above were the only ones seen in which the number of red corpuscles sank below 1,500,000 to the cubic millimetre with absence of nucleated red corpuscles. In examining stained specimens for the presence or absence of such corpuscles it is necessary to use a mechanical stage, and to make a thorough millimetre search of at least ten specimens. Several times the writer has failed to find nucleated red corpuscles in the first few specimens examined, only to find one in the fifth or sixth specimen. Where the blood is smeared on the slide instead of on the cover glass, such a specimen is equal to three or four cover-glass specimens—so that the examination of three "slide" specimens would be sufficient.

Many cases were met with which showed an extremely small number of red corpuscles with the presence of nucleated red corpuscles in varying numbers. It would make this article too long to quote any of these cases, of which a typical example was reported by the writer in the *Medical News*, October 16, 1897, under the title of *A Case of Infantile Malarial Fever with Grave Anaemia*. The presence of nucleated red corpuscles in the blood by no means warrants a favorable prognosis, their very presence being an indication that the blood-making organs are being pushed beyond their limit of production of normal red corpuscles. Many such cases prove fatal, as, for example, those of typical progressive pernicious anaemia. But, on the other hand, many end in recovery, as in the case quoted above. Where the red corpuscles are above 1,500,000 to the cubic millimetre (to be conservative) the presence or absence of nucleated red corpuscles is of little significance; but where they are below that number, and where no nucleated red corpuscles are to be found, a fatal result may be confidently expected.

THE CARNegie LIBRARY

RETENTION OF URINE.

By RAMON GUITÉRAS, M.D.

THIS term designates an inability, on the part of the bladder to empty itself on a constant or occasional obstruction. It is variously characterized as complete or incomplete, according to the degree of obstruction; acute or chronic, depending upon the duration; and variety of the attack; and traumatic, organic, or obstructive, referring to the nature of the cause.

* Read before the Society of the A. M. of the City of New York, December 11, 1898.

Complete retention, from whatever cause, is a condition in which the patient can not pass any urine from the bladder; it is incomplete when he can empty it only in part, a certain residuum, of from a drachm to a pint, always remaining in the bladder; the urine which passes represents the excess over this residuum. Acute retention occurs when the patient suddenly finds that he can not pass any urine, though he may never before have had any difficulty; it is chronic when for a long time he has not been able to empty his bladder; and paralytic when his inability to void urine is due to paralysis of the bladder wall or to a lesion of either brain or cord.

Retention is obstructive when, owing to some growth or impediment in or about the neck of the bladder or urethra, either no urine or not all of it can be forced out; it is traumatic when some wound gives rise to an impediment either in the urethra itself or on the outside which presses upon it.

Occasional acute attacks of retention may be due to operations, alcoholism, profound temporary stupor, or voluntary refraining from urinating; all other cases are dependent upon chronic conditions and are attended with a loss of power in the bladder wall. It applies as well to paralytic as to obstructive cases. The loss of power is variously referred to as paralysis, paresis, and atony. There is really very little difference between certain degrees of these conditions. Complete paralysis of the bladder is found when on account of some brain or cord lesion it is incapable of expelling any urine. Paralysis is partial when the bladder is not able to empty itself fully; paresis is another name for partial paralysis; and atony is a condition where through lack of power the bladder wall can not force out all its urine. Some writers try to explain this difference by saying that paralysis is a condition where the action of the detrusor and the sphincter muscles is completely suspended, while in atony the contraction of the organ is feeble, slow, and imperfect. Coulson says that many refuse to admit the existence of paralysis, excepting when the motor centres are affected. He thinks that the stretching of the nerves of the bladder wall in retention injures them and interferes with their reflex activity, thereby being just as much a cause of atony as the loss of contractile power of the muscles. He thinks it probable that peripheral affection of the nerves may be caused by an overdistention of the bladder. Where the nervous irritability is diminished, but not lost, the contraction of the muscular wall feeble, and a state of partial paralysis or loss of power present, we may use the term atony or paresis of the bladder.

Others say that atony of the bladder is lack of expulsive force due to failure on the part of the muscles, the nerves remaining sound, and that paralysis is the same condition, only more pronounced and due to central origin. At any rate, both in atony and in paralysis, the bladder may be constantly distended by urine to a certain extent, perhaps to its utmost limit, as a passive

sack, and the excess of this residuum may dribble away involuntarily (false incontinence); or it may be expelled in small portions by repeated acts of urination in the ordinary way with the aid of great straining and assistance of the voluntary contractions of the muscular wall of the abdomen.

The causes of atony are: overdistention by neglecting to urinate, involuntary retention in cases of fever and coma, and urethral obstructive conditions. The muscular coat of the bladder may be paralyzed from any cause that will induce loss of muscular power in other parts of the body, and the paralysis may affect either the detrusor urinæ, or the sphincter vesicæ, or both at the same time. Power may be diminished or wholly lost, and this impairment of function may be temporary or permanent.

The muscles of the bladder which expel or retain the urine are only partially under the control of the will. Thus the contraction of the detrusor is involuntary, being occasioned as a reflex from the stimulus of the urine in the bladder. When sensibility is diminished and the presence of urine no longer acts as a stimulus on the detrusor, the result is urinary retention. The exact location and nature of the sphincter is still a matter of dispute. According to some authorities, the circular fibres serve to close the viscus at its neck, while others regard the compressor urethræ as an external sphincter, although it probably aids only in the expulsion of urine. Still, it is true that this muscle, the compressor urethræ, must relax under the influence of the will before the contents of the bladder can escape.

It is well to remember also that the bladder muscle may be directly paralyzed by overdistention, as already stated, or by inflammation extending from either its mucous or its serous coat.

CAUSES.

Acute Retention.—Acute or temporary retention may be due to operations on or about the external genitals, anus or rectum, or upon parts of the body quite distant from this locality depending upon a spasmodic inability to urinate. It may also be due to acute alcoholism or to large doses of opium, belladonna, or hyoscyamus, especially when given by rectum. Profound temporary stupor, such as occurs in typhoid fever or other prostrating diseases, causes it at times. Voluntary refraining from urinating, although the desire may be very great, as when one is in company in a place where there is no opportunity, and holds his urine until the bladder is so full that its walls are unable to contract, is also at times a cause of retention. It may also be found in pregnant women, due to some displacement of the uterus, which thereby presses upon the bladder. If it occurs after delivery, it is due to displacement of the bladder or to the effect of long pressure upon its neck by the child's head.

Acute attacks may also occur during chronic ob-

structive conditions, such as stricture or enlarged prostate from various causes.

In the majority of cases retention is due either to organic nervous lesions or to obstructions involving the urethra.

CHRONIC RETENTION. *Certain Organic Nervous Diseases Cause Retention.*—In paraplegia, in hemiplegia, and in locomotor ataxia we may have complete or partial retention due to motor paralysis.

In Pott's disease we may have retention with incontinence, due to paralysis by interference with the vesico-urethral nerve centres.

In injuries of the brain and spinal cord the same applies. These are attended by important changes in the urinary system as well as in the urine. These changes do not seem to be connected with the particular locality of the injury. They occur almost uniformly, whether the injury affect the lumbar, the dorsal, or the cervical region.

In the various forms of spinal sclerosis there may be more or less complete retention, in the earlier stages of a spasmodic nature (during the stage of excitement), and later, due to paralysis.

The Obstructive Causes.—They are principally situated in the prostate or the urethra, although occasionally pedunculated tumors or vesical calculi may swing into the neck of the bladder and engage there. Displacement and fracture of pelvic bones, especially of the pubes, may also cause obstruction.

Prostatic causes of obstruction are acute prostatitis, and hypertrophy, tumors, cysts, concretions, or tuberculosis of the gland.

The urethral cause is usually a stricture. The retention may be due to an acute congestion of the mucous membrane or of the submucous tissue about this lesion, or it may be a late symptom dependent upon the great obstruction offered by the stricture itself. In either case it is apt to be preceded by a history of fatigue, cold, and alcoholic excesses. Spasm of the urethra aids in closing the canal. Foreign bodies, calculi, blood clots, and polypi of the urethra may also cause retention.

Atresia is another cause. This may give rise to complete retention in the newborn if the urethra is impervious; or, if it is slightly pervious, the trouble will come on gradually. This latter condition is really a congenital stricture.

Wounds of the urethra also give rise to retention, either by causing a congestion or an exudate which narrows its calibre, or by pressing upon its walls on the outside, and thus rendering it impervious.

Extravasation of urine, due to rupture of the urethra from an injury or wound, or to rupture of a urethral follicle, may allow sufficient leakage of urine into the surrounding tissues either in the pendulous portion of the urethra or the perineum, to completely block the canal by its pressure.

Abscesses or cellulitis starting in the urethra or sur-

rounding tissue may also exert enough pressure upon the urethra to shut it off.

Symptoms.—The symptoms of retention vary in a marked degree.

In an acute attack, such as occurs after an operation or during a fever, the patient complains of pain steadily increasing in the region of the bladder, and a sense of fullness and inability to micturate, associated with a constant desire. On pressure over the pubes there is a feeling of tenderness and distention, and perhaps a globular tumor can be made out extending up above the pubes toward the umbilicus. Rectal examination will usually reveal a tumor filling the pelvis like a gravid uterus.

Chronic complete retention rarely occurs, as it is usually associated with incontinence. It may be observed, however, in certain cases of paralysis or obstruction. In complete retention, such as occurs in some cases of paralysis, the patient may not have been able to void a drop of urine for months. He knows, however, when his bladder is full, either by the sensation, or, in cases of paralysis where sensation is not perfect, by the knowledge of how long it takes it to fill, and he has learned at these intervals to have recourse to his catheter.

In a chronic case of incomplete retention the symptoms are also different. In this class all cases tend to have residual urine, and the condition develops so slowly that the patients often do not know that they can not empty their bladders until they have been so informed by the physician after an examination. A man with a weak bladder may carry about a pint or more of clear urine in this viscus for many years as a residual deposit, which its weakened walls can not throw off. An excess of the fixed residuum produces a desire to urinate, and the patient, mainly by voluntary contraction of the abdominal muscles, is able to void this excess.

Acute attacks of retention in cases of chronic incomplete retention occur principally where there is obstruction to the escape of urine in the form of stricture or enlarged prostate, and in this latter class of cases it is very common.

A patient with prostatic hypertrophy suffers from chronic incomplete retention, in addition to which his bladder is usually atonic and chronically inflamed. The usual symptoms are those of cystitis, pain, frequency of micturition, and the passage of a thick, foul-smelling urine. After overeating or drinking, or exposure to cold or to wet, these patients suddenly find that they can not pass urine. As the bladder dilates they have a feeling of pain and a sense of retention, which is usually relieved by the methods which we shall mention under "Treatment."

Cases of acute attacks of retention due to stricture are also common. Here also there is usually a certain amount of residual urine in the bladder. In bad cases the urethra behind the stricture is dilated, at times even

as far back as the neck of the bladder, which itself becomes dilated and no longer acts as a sphincter. The urine involuntarily escapes through the stricture in a sitting or a standing position. Here it is often difficult to expel the urine. Great straining and prolapse of the rectum may accompany the act. Retention with incontinence at the same time may occur here, as the urethra and bladder behind the stricture are full of urine, which can be discharged only at times by leaking through the stricture.

In all these cases, where the bladder can not empty itself, retention becomes chronic. Cystitis develops, together with residual urine. The contents are partly evacuated with each act of micturition, yet some pus, bacteria, and alkaline urine remain in the bladder to contaminate the fresh urine flowing into it.

Note.—The contractile power of the bladder becomes insufficient to expel the urine, and the result is residual urine. The bladder wall becomes stretched and atonic. The distention may increase until the sphincter relaxes and the urine dribbles away.

Diagnosis.—When we are called to see a case of retention of urine we must first ascertain if it really is retention, and then inquire carefully into the history of the case, whether it is complete or incomplete, and if complete, whether it is an acute attack or not; and if an acute attack, whether the patient has had others of a similar nature. We should then notice if he has any other symptom, general or local, which can give us some clue as to the cause of retention; also inquire into his age and family history.

To be sure that he has an attack of retention, there are certain other conditions that we must exclude, as suppression, rupture of the bladder, and extravasation of urine.

It is strange how generally suppression and retention are confounded with one another. Suppression is a condition where the function of the kidney has ceased, and retention where the bladder can not empty itself. If no urine can be passed by the urethra, and it is a question between suppression and retention, a bimanual examination per rectum and suprapubically will disclose the presence of a large fluid tumor in the latter case, and a catheter inserted into the bladder will draw off a quantity of urine in the latter case and none in the former.

Rupture of the bladder can be distinguished from retention, as in the case of the former there is no well-defined globular tumor present, and a catheter passed by the urethra will bring away only a slight amount of urine and blood. The patient will complain of great pain and tenderness in the suprapubic region, and tympanites, an elevation of temperature, and rapid pulse will quickly follow.

In extravasation of urine the bladder may be quite full on account of the pressure of the exuded urine on the urethra; it may be impossible, however, to pass

an instrument into the bladder on this very account. The extravasation can be seen as a tumor in the perineum or external genitals.

The history of a case of retention will reveal a great deal to us, as will a survey of the symptoms. For instance, if there is a history of an operation on the genitals or about the rectum, an acute attack of retention can be ascribed to that source. If the patient has had a fall and is paralyzed below the waist, it would indicate a retention due to paralysis. Likewise, if he has had a stroke of apoplexy, or a fracture of the skull, or is suffering from transverse myelitis, and we see other evidences of paralysis, we can assume that the retention is due to this cause and not to any local condition. To show that injury to the cord is followed by bladder dilatation, I will quote an experiment of Budge, who found that division of the cord in the lower dorsal region was followed by increased reflex action of the sphincter and a greater degree of distention of the bladder than could be produced after death.

It is rare that retention is so complete that not a drop of urine can be passed, but we do observe cases in complete and partial paraplegia where not a single drop can be voided without the catheter.

Having excluded paralysis as a cause of retention, we should then look for some local trouble to account for it. If the man is over fifty-five years of age and has a history of trouble in urinating, the stream coming tardily; and if he suffers from such frequency of urination as to be obliged to get up frequently at night; and if, on certain occasions, he was unable to pass his urine except when aided by a hot bath or by hot local applications, we can assume that he has some prostatic trouble, and can examine him per rectum and per urethram to see if obstruction is present there. If an enlargement is found, it is probably occasioned by senile prostatic hypertrophy. Of course, there are other prostatic troubles that may give rise to enlargement, as malignant tumor, tuberculosis, and cystic conditions, but these are rare.

If the patient is a man between twenty-five and fifty years of age, who has had several attacks of urethritis, and has recently urinated with increased frequency and with some difficulty and pain, his urethra should be explored for stricture, and if one of small calibre is found it is probably the cause of his retention.

When it has been determined in chronic cases of retention that residual urine is present, it is well to consider the condition of the bladder. We can form some idea of the tone of its wall by introducing the catheter. If there is no atony, the stream rushes through the catheter until the viscus is emptied. If there is atony, it will run out slowly, and toward the end is influenced by the breathing. In all cases of retention we must ascertain the presence or absence of cystitis, and if it is not present, we should use every effort to prevent it. Cystitis is caused by congestion and infection. In cases of retention, due either to paralysis or to

obstruction, there is distention of the bladder walls with consequent congestion. This is favorable to the production of cystitis, if the exciting cause (or infection) is carried in by the catheter.

Patients with cystitis may suffer agony from pain, frequency of urinating, and tenesmus. Others may have a flabby bladder, discharging stringy mucus and ammoniacal urine, with no other symptom than a sense of weight in the lower abdomen and a frequent desire to urinate. Motion, such as jolting and rough riding, may cause pain in the hypogastrium, perineum, and end of the penis associated with a frequent desire to urinate.

(To be concluded.)

INHIBITION.*

By S. J. MELTZER, M. D.

(Continued from page 656.)

Reflex Inhibition.—In the systems we have thus far examined the inhibition has been found to be present in the peripheral ends of the nerves, and is to be obtained by stimulation of the peripheral end of the divided nerves—for instance, the peripheral end of the vagus, the splanchnicus, the lingual nerve, etc. But we have also met with instances of reflex and central inhibition—for instance, the inhibitions of respiration, of deglutition, the stimulation of the nervus depressor, the inhibition of the heart by the stroke experiment of Goltz, the inhibition of the lymph hearts, etc. We are now going to tabulate inhibitory phenomena mostly occurring in the skeletal muscles and brought out by reflex stimulations from some part of the skin or from the central end of a non-specific sensory nerve.

The above-mentioned stroke experiment—i. e., the inhibition of the heart beat by striking the abdomen of a frog—can not occur, according to Goltz (86), if at the same time the leg is pinched. On the other hand, the pinching of the leg does not cause any reflex movement if the abdomen is struck at the same time. A frog without hemispheres responds promptly to every gentle stroke on the back with a croak; this phenomenon is known as the croak reflex (Goltz (87)). This reflex also is suppressed by a stimulation simultaneously applied to the leg [Goltz (88)]. Schlösser (89), however, states that the reflex is prevented not by inhibition but by an antagonistic reflex causing the closure of the glottis. If the leg of a decapitated frog is immersed in a solution of sulphuric acid it is withdrawn after a certain interval. This interval is prolonged if the other leg is pinched at the same time. All reflex movements of the legs are immediately inhibited when the skin on the back or on one arm is subjected to a chemical, mechanical, or electrical stimulation [Lewison (90)]. If the central end of the sciatic nerve of one side of a decapitated frog is stimulated with the induction coil for some time, only a short reflex movement of the other leg occurs

at the beginning of the stimulation, and another movement at the interruption of the current, but there is absolute rest during stimulation. And during stimulation the leg is not withdrawn from acid if it is immersed there [Setschenow (91), Nothnagel (92)].

If a decapitated snake is suspended by its upper end the body regularly makes rhythmical, pendulous movements. These movements stop immediately as soon as the body is gently touched [Luchsinger (93)]. According to Langendorff (94), stroking over the region of the tympanum or eye of a frog causes throwing movements of the leg of the opposite side: this reflex, too, is inhibited by stimulation of a sensory nerve. Goltz (95) and Freusberg (96) have reported a number of reflex inhibitions which they have observed in a dog whose spinal cord was divided in the thoracic region. In this animal the anal sphincter showed rhythmic contractions, which could be stopped by squeezing the foot; there were also frequent contractions of the rectum, which could be inhibited by pinching the skin. When a thermometer was introduced into the rectum it was immediately pushed out; but was made to stay there by pinching the skin of some part of the abdomen. Brown-Séquard (97) observed the rhythmic contractions of the sphincter in guinea-pigs even when there was only a hemisection of the cord; here, too, the contractions were inhibited by squeezing the foot. Erections could be caused by certain reflex stimulations, but were promptly inhibited by electrical stimulation of the anal skin or the testicles. Reflex micturition could be inhibited by stimulating the legs. When the dog was in a fasting state the hind leg used to show rhythmic pendulous movements, which could be inhibited by pinching the tail.

Boubnoff and Heidenhain (98), in their experiments on the cortex of the dog, report that under morphine anaesthesia a tonic contraction of the leg was easily brought on, but could be made to relax by a gentle mechanical or electrical stimulus applied to the skin of the same side.

Sherrington (99) found that stimulation of the central end of the sciatic nerve inhibits the knee-jerk. The same can be attained by stimulating the central end of the nerve of the flexor muscles of the thigh, or by squeezing the central end of the flexor muscles, or by gently stretching them (100). All these manipulations relax the tonus of the extensor and inhibit the knee-jerk. These observations, however, are perhaps not to be classified among the reflex inhibition phenomena, since the pendulum seems to swing at present in the direction of the belief that the knee jerk is of muscular origin. In a previous communication Sherrington (101) reported having obtained a tonus of the extensor of legs and arms in dogs whose brains had been cut at the level of the crura cerebri. This tonus he could inhibit by stimulating the skin of the extremities or the central end of

the corresponding nerves, and even of the dorsal nerve root. In a very recent communication Sherrington (102) further reports that in the removal of the cerebral hemispheres he has discovered a reliable method of obtaining general extensor spasms, which he terms "decerebrate rigidity," and which is developed and maintained by centripetal impulses coming from each corresponding limb. In such an animal with "decerebrate rigidity" the reflex inhibitory phenomena are striking, and can be demonstrated with the greatest ease.

Inhibition from the Central Nervous System.—Leaving now the peripheral inhibitory reflexes as well-established phenomena, we turn our attention to the central nervous system. Setschenow (103) has found that stimulation of the thalami optici and corpora quadrigemina increases the reflex time—i. e., that a frog withdraws his leg from a solution of sulphuric acid much later if the above-mentioned parts were stimulated at the same time; he therefore believed that inhibitory centres for the spinal reflexes were located within the optic thalami and the quadrigeminal bodies. We shall not speak here of the long and lively discussion which followed this assertion. According to Ott and Woodfield (104), the optic thalami contain a centre for the inhibition of the peristalsis. It has already been mentioned above that Pflueger and Pal have obtained inhibitions of the peristalsis by stimulation of the spinal cord. Sherrington (105) obtained inhibition of the decerebrate rigidity by stimulating the dorsal spinal columns in the cervical region. Sherrington, as well as Horsley and Löwenthal (106), obtained inhibition by stimulating the surface of the cerebellum.

With regard to the cerebral cortex we have to recall here again that Bounbnoff and Heidenhain were the first ones to observe that under certain conditions stimulation of the cortex had an inhibitory effect upon the tonic contractions of some extensor muscles. The recent important observations of Sherrington, however, shed a bright light upon our subject. In experiments made together with A. E. Hering (107) upon monkeys, which, when in a certain state of anaesthesia, show a rigidity of the muscles, it was found that in stimulating the cortical area for the flexors these muscles contracted, while at the same time their antagonists relaxed, and in stimulating the area for the extensors these muscles contracted while the flexors relaxed. In the paper on these experiments, as in the paper on the decerebrate rigidity, Sherrington points out the remarkable fact that the cortical area for inhibition of a group of muscles coincides not with the area for contraction of this group, but with the area for contraction of the group of muscles antagonistic to it. In another series of experiments Sherrington (108) has cut the third and fourth cranial nerves of the left side in monkeys, which paralyzes all the eye muscles except the rectus externus. There was then no muscle left which could by active contraction move the eye to the right. Nevertheless,

when the cortical area in the frontal or in the occipital region was stimulated, which usually produces conjugate movement of both eyes to the right side, also the left eye was seen promptly moving to the right until it reached the median line, which can only mean that the tonus of the left rectus externus, which kept the eyeball turned to the left, was inhibited by the cortical stimulation and thus permitted the eye to return, by the force of the elasticity of the surrounding tissue, to the normal position. The same result was obtainable when the cortex was removed and the corona radiata or the internal capsule was stimulated. The inhibition in question probably takes place in subcortical centres. Topolanski (109) has verified this statement of Sherrington's by the graphic method. He removed the anterior insertions of the rectus externus and the rectus internus from the eyeball of a rabbit and connected them with levers marking the movements on a kymograph, and he found that a cortical stimulation which caused the contraction of one muscle caused at the same time the elongation or relaxation of the antagonist. In connection with this remarkable series of experiments of Sherrington's, the first part of which appeared in 1893, I may be permitted to quote part of a passage of an article of mine (110) published in 1883, which reads as follows: "Of a purposeful arrangement we could expect that, for instance, a nerve, the stimulation of which causes flexion, ought to contain also inhibitory fibres for the extensors. Now, such an arrangement is indeed present—at least in one function—namely, in the respiratory mechanism. Of the superior laryngeal nerve, of the second branch of the trigeminus, and of the splanchnicus, we know that stimulation of their central end causes inhibition of the inspiratory and contraction of the expiratory muscles." But the following quotation, which I can not restrain myself from giving in full, is indeed a marvel. It reads as follows:

"The nerves have been considered so generally as instruments for stimulating the muscles, without thought of their acting in the opposite capacity, that some additional illustration may be necessary here. Through the nerves is established the connection between the muscles, not only that connection by which muscles combine to an effort, but also that relation between the classes of muscles by which the one relaxes and the other contracts. I appended a weight to a tendon of an extensor muscle, which gently stretched it and drew out the muscle, and I found that the contraction of the opponent flexor was attended with a descent of the weight, which indicated the relaxation of the extensor. To establish this connection between two classes of muscles, whether they be grouped together as in the limbs, or scattered widely as the muscles of respiration, there must be particular and appropriate nerves to form this double bond to cause them to conspire in relaxation as well as to combine in contraction."

So in 1826 said Charles Bell.* Twenty years before the discovery of the effect of the vagus upon the heart, inhibition was a natural supposition to this great mind, and not only did he expect to find it in all muscle groups, but tried to establish by an actual experiment the presence of the mechanism for the contraction and relaxation of antagonistic groups of muscles, a mechanism which is now termed by Sherrington "reciprocal innervation."

Returning to inhibition within the central nervous system, I have to record here the fact that an impulse which causes inhibition in a centre attending to a specific function, irradiates, spreads from there to other centres and functions which neither anatomically nor physiologically are directly connected with the primary centre. I (111) have shown that the inhibition which appears in the centre of deglutition during each swallow diminishes the tonus of the cardio-inhibitory and the vaso-motor centres, inhibits respiration and affects centres located in the lower part in the spinal cord, and may even inhibit reflexes caused by peripheral stimuli. Hering (112) observed that distention of the lungs, which sends an inhibitory impulse to the centre of respiration, depresses also the tonus of the cardio-inhibitory and the vasomotor centres.

Inhibition in Voluntary Acts.—It is an interesting and important question how much, if any, inhibition is involved in the suppression of the so-called voluntary movement. Eduard Weber (113) has from the start compared the cardiac inhibition to the voluntary suppression of the tonic contractions of the sphincter ani and vesicæ. But this suppression can be interpreted as an act of pseudo-inhibition, inasmuch as it could be maintained that the voluntary contraction of the muscles of the abdominal wall simply forced the contents of the rectum and bladder through the contracted sphincters. That the soles are not withdrawn when they are tickled, or that we do not laugh when we have cause for it, which facts have been adduced by some as instances of voluntary inhibition, can also be explained by the fact that either we have trained the muscles antagonistic to the movement of these reflexes, or that the involved centres have lost their sensitiveness. In the discussion on this subject some writers have brought forward the assurance that they can voluntarily inhibit sneezing, and even yawning, without the aid of antagonistic muscles. But it is only an assertion, and not a proof. The voluntary interruption of a voluntary movement seems to me mostly accomplished by the aid of the antagonistic muscles, even if inhibition, too, is involved in the act; and we might expect this the more since Sherrington has shown that the cortical area for inhibition coincides with the area of contraction of the antagonistic muscles, and thus the impulse originated in this area might affect both fac-

tors at the same time. With regard to the voluntary interruption of a reflex inspiration, Gad (114) asserts that according to his observation on himself the interruption is simply inhibition without the aid of the expiratory muscles, and hence his conclusion that the inspiratory command to the diaphragm must be of the nature of tetanus and not a single impulse. This, too, is after all only an assertion which is hard to prove, as I know by my own observations on myself. It seems to me, however, that the observations of Bowditch and Warren (115) on the reinforcement of the knee-jerk by a voluntary contraction of some muscles can be adduced as a proof for the involvement of an inhibitory impulse in the voluntary movements. These investigators have found that if the voluntary contraction precedes the blow on the tendon by a perceptible interval the result is rather an inhibition than a reinforcement of the knee-jerk, which would seem to demonstrate that with each contraction a wave of inhibition runs ahead of the wave of contraction. Quite a sure proof, however, of the actual participation of inhibition in voluntary movements is to be found in the above-quoted experiment of Sherrington's on the eye muscles of the monkey. The animals whose left third and fourth cranial nerves were cut, so that the rectus externus alone was under nervous control, could, after the recovery from the operation, follow with the left eye all the movements of an object—food, for instance—which was held in front of them. Of course, the object had to be on a level with the eye, and the movements could go to the right no farther than the median line; but the eye moved slowly, or rapidly, or suddenly, according to the movements of the object, just as a normal eye would do, while, in fact, the movements were regulated only by the voluntary inhibition of the tonus of the rectus externus.

That the voluntary movements may be inhibited by artificial stimuli has been reported by A. Fick (116), who has observed the disappearance of a normal maximal contraction upon the application of an electrical stimulus. Waller (117), however, insists, as mentioned above, that the disappearance is due only to the contraction of the antagonists. A. Cleghorn (118), experimenting in the Harvard physiological laboratory, has recently found that an artificial stimulus quickens the normal voluntary relaxation, and by special arrangement he has excluded the participation of the antagonists in this process.

Inhibition of Sensations.—I have thus far dealt with the central inhibition of such afferent impulses, the natural destination of which was to be carried out again from the central organ to the periphery. Of the inhibition of afferent impulses for which the central organ is the end station, and the presence of which can be recognized only by their appearance in the narrow path of our consciousness—in short, of inhibition of sensory impulses—I can make only a very scant statement. The subject has practically not yet been studied, either

* *The Anatomy and Physiology of the Human Body*, by Charles and John Bell, London, 1826. John Bell died in 1829. See Sherrington, *Proceedings of the Royal Society*, vol. lili, p. 115.

by physiologists or by psychologists. Although a number of instances could be adduced here which would seem to demonstrate the actual existence of a central as well as a reflex inhibition of sensations, such a course would be practically an original contribution, and is beyond my task here, which I have restricted to the recording of well-established observations stored up in our literature. And here I can record only the following few observations on the inhibition of sensation. Setschenow (119) states that the painful sensations which an acid produces when a hand is immersed in it can be retarded and diminished by tickling any other part of the body. According to Urbantschitsch (120), the characteristic sensations which a galvanic or induction current causes when applied to a part of the body are immediately diminished when another current is applied to some other part of the body. Furthermore, when one hand is immersed in hot or cold water and kept there until a burning sensation is felt, this sensation is distinctly diminished for a while immediately upon dipping the other hand also into hot or cold water. Exner (121) illustrates sensory inhibition by a well-known optical experiment, for the description and analysis of which I have to refer to the book of this author.

Inhibition in Muscle-nerve Preparations.—The inhibitory phenomena which were hitherto presented to occur either in the central nervous system or at the ends of peripheral nerves terminating in the viscera. It has been surmised by many writers that inhibition can occur only in nerve centres, and that in the peripheral phenomena inhibition takes place in the nerve cells which are to be found in the heart or in the walls of the gastrointestinal canal. In the blood-vessels, however, so far, at least, no nerve cells have been discovered, and there we have to assume that the vaso-dilators exert their influence directly on the circular muscle fibres of the vessels. I shall record a few more inhibitory phenomena taking place in muscles in which no cell ganglia could be demonstrated. I have already recorded above the distinct inhibitory effect which was studied by Langley and Anderson on the retractor muscle of the penis of the dog. Fletcher (122) reported recently that he could demonstrate the inhibition of the retractor muscle in the hedgehog, and that by the methylene-blue method he had established the absence of nerve cells in this muscle, which consists of plain muscle fibres. Pawlow (123) has stated that by stimulating the nerve of the closing muscle of the anodonta he has observed the relaxation of this muscle when it was in a tonic state, and in this muscle, too, no nerve cells could be discovered. The studies of Biedermann (124) on the muscles of the claw of the crawfish are most interesting. When the abductor was divided and the nerve of the claw was stimulated, it was found that a moderate stimulus caused a relaxation of the tonically contracted adductor, while a stronger stimulus caused its contraction; but when the adductor was cut and the nerve stimulated, the abductor muscle

contracted with a moderate and relaxed with a strong stimulus. When each muscle was separately connected with a lever graphically marking their movements, and the stimulation of the nerve was gradually increased, it was found that the first effect was that of the contraction of the abductor; next came the relaxation of the adductor; and then followed the contraction of the adductor, and about simultaneously with it the relaxation of the abductor took place. These experiments show that each muscle is provided with inhibitory and motor nerves, but that in the abductor it is the motor nerve which is more sensitive, while in the adductor it is the inhibitory nerve. The result is that a stimulus which is sufficient to contract the adductor keeps the abductor relaxed, and that a stimulus which causes the contraction of the abductor either causes directly the relaxation of its antagonist, or is at least insufficient to cause its simultaneous contraction. This is a beautiful example of purposeful reciprocal innervation, as Sherrington terms it, which in this case takes place strictly in the periphery, as the experiments were made on an amputated leg. It should be added that the muscles under question consist of striated muscle fibres.

In the few instances which I have just quoted the muscles either consisted of unstriated muscle fibres, or they belonged to invertebrate animals. There are, however, a few instances which tend to prove the presence of inhibition in the muscle-nerve preparation of the vertebrates also. The immersion of a nerve of a muscle-nerve preparation of the frog in glycerin causes a tetanus of the muscle. C. Kaiser (125) has found that the tetanus is inhibited when an electrical or chemical stimulus is applied to the nerve at the point central from that which is immersed in glycerin. A tetanus can also be brought on by permitting the central end of the nerve to dry out. Wedenski (126) has found that after subsidence of the tetanus, maximal stimuli applied to the nerve fail to elicit any response from the muscle, but the stimuli are immediately effective as soon as the dried-out part of the nerve is cut off, which apparently goes to show that the dried part of the nerve was exerting an inhibitory effect upon the muscle. Both Kaiser and Wedenski believe that the inhibitory process takes place within the nerves, perhaps within the end plates of the nerves, but not in the muscle.

There is, however, some evidence that inhibition occurs, or can occur at least, in the muscle tissue itself. For the striated muscles of the vertebrates we know that the galvanic current causes a contraction only by the making and the breaking of the current, and that the making causes the contraction at the cathode, while the breaking causes the contraction only at the anode. Now, Biedermann (127) has found that in the bodies of some invertebrates, in organs with unstriated muscle fibres, and in the muscles of the heart, with the making of the current there is an inhibition at the anode, and with the breaking there is an inhibition at the cathode. That in

the striated muscles of the vertebrates only the contractions are noticed, and not the inhibition, has to be explained by the relaxed state of the muscle, which, of course, would not show the effect of inhibition. Biedermann (128) therefore has experimented with the veratrinized sartorius muscle of the frog, which shows a very slow relaxation after the contraction caused by stimulation. When a galvanic current was applied in this tonic state, it was found, indeed, that there was a rapid relaxation at the anode with the making, and a moderate relaxation at the cathode with the breaking, of the current. And as the same result was obtained when the animal was also curarized, and as curare excludes the possible participation of the end plate of the nerves, this experiment can be taken as a proof that the inhibition was taking place in the muscle tissue itself [Piotrowski (129)].

This is the place to mention the discovery of Gaskell (130), that stimulation of the peripheral end of the vagus caused a positive variation of the muscle current in the hearts of the tortoise and the crocodile, while stimulation of the accelerating nerves of the heart caused, as usual, a negative variation (131). Furthermore, Biedermann (132) found that in stimulating the nerve of the claw of the crawfish with such currents as cause an inhibition of the muscles, the muscle current showed a positive variation, while, when the stimulation was of such an intensity as to produce a contraction of these muscles, the action current consisted of a negative variation. These authors, therefore, maintain that there is indeed a causal connection between the contraction and negative variation on the one hand, and inhibition and positive variation on the other hand.

(To be concluded.)

THE TERM APPENDICITIS,

AND OTHER UNSCIENTIFIC WORDS OF OUR NOMENCLATURE.*

By ACHILLES ROSE, M.D.,

CORRESPONDING MEMBER OF THE Χρυσταλίνη Ἀρχαιολογική Ἑταιρεία,
OF ATHENS.

ON a former occasion I promised to inform myself which word our Greek colleagues were employing for the term appendicitis, a term which is, naturally enough, an impossibility among Greeks. I wrote to Dr. Theodore Zaimis, of Patras, a prominent surgeon whom I had had the pleasure to see personally while visiting Greece. His answer is as follows:

Πάτρας, τῇ 20 2 Ἰανουαρίου, 1899.

Σεβαστὲ μοι Συναδέλφει,

Ζητῶν ἀναγγεῖν διὰ τὴν ἐπὶ μικρὸν βρωδιῶσαν ἀπατησίαν μου, ἐπιλοῦσθαι ἕνα ἀπαισιῶν μου ἐκ Πατρῶν, ἀπειδὴ ἐπανελθὼν εἰς μεταδωτο ἱστὴν πᾶν εἰχαίματος τας ἐξως πλῆμφορίας περὶ τοῦ ζητουμένου.

Ἐν τοῖς ἀρχαίοις συγγραφαῖς ἡ νόσος οὔτε περιγράφεται, οὔτε σαφὲς ὀνομάζεται. Ἡμεῖς χρώμεθα τοῦ ὅρου "περιτεφυλίτις," "παρυτεφυλίτις" καὶ "σκοληκοειδίτις" ὁ τελευταῖος ὅρος ἀπαποκρίνεται ἀκριβῶς εἰς τὸν ἰμέτερον "appendicitis," ὁμοίως ἡ appendix καλεῖται παρ' ἡμῶν "σκοληκοειδὴς ἀψύφοντις," ἐπειδὴ ὅμως κατὰ τὴν σκοληκοειδίτιδα συμπύκναι καὶ τὸ τυφλὸν ἰδίᾳ δὲ τὸ ὄρθως αὐτοῦ περιβλήμα, δηλαδὴ τὸ περιτόναιον, τοῦτον ἕνεκα χρώμεθα τοῦ ὅρου περιτεφυλίτις πολὺ σιγώτερον διὰ δὲ τῆς ὀνομασίας "παρυτεφυλίτις" ὁρλοῦμεν τὴν ἐπίστατον τῆς φλεγμονῆς εἰς τὸν συνδετικὸν ἰσθμὸν τὸν κατὰ τὴν εἰλεακὴν χώραν.

Εἰχαριστῶν ἀπὸ καρδίας τὴν εὐγενεστάτην δεσποινίδα Rose, εἰχομαι ἱμῖν τε καὶ τῇ δεσποινίδι, πᾶσαν εὐτυχίαν καὶ πᾶν ἀγαθόν.

*Ὅλος ἰμέτερος

Θεόδ. Ζαΐμης.

It reads in English: "Patras, January 2, 1899. My respected colleague. Asking pardon for my long delay in answering, caused by my absence from Patras, I hasten, as soon as I have returned, to give you with much pleasure the following information on the subject:

"The disease in question is neither described by the old authors, nor mentioned distinctly. We use the terms 'perityphlitis,' 'paratyphlitis,' and 'scolecoiditis,' the latter corresponding exactly with your 'appendicitis,' because the appendix is called by us scolecoides apophysis, but since during scolecoiditis the typhlon, and particularly the serosa covering it—namely, the peritoneum—are likewise affected, we use the term perityphlitis much oftener. By the term paratyphlitis we mean the extension of the phlegmonous process to the adjoining tissues in the iliac region," etc.

Before discussing the homely word appendicitis, I wish to say that I shall be obliged to the scholar, the student of classical philology, the Hellenist, who can point out in this letter of Dr. Zaimis's, or in the Greek translation of Niemeyer's *Pathology* (should read *Nosology*) and *Therapy*, or in Λοεκά Παταϊώων Ἀνατομὴ τοῦ Ἀνθρώπου, or in Zaimis's monograph Περί τῆς θεραπείας τῶν ἐν τῇ κοιλότητι τῆς κοιλίας καὶ τοῦ τυφλοῦ ἀπατησιῶν κεντέρων ἐξιντοκόκκων, which books I am placing here before you, or in any scientific medical work in the Greek language of to-day, a single word which is new Greek—that is to say, new Greek as most people erroneously imagine it to be. I shall reward him by exerting myself to hunt up a book which has been written, since the time of Luther, in pure, unmixed German.

There exists, indeed, a new Greek which merits all derision, because it is, as Hyrtl and others have called it, ridiculous, puerile, because it is silly; this is the Ἑλληνοφασίς language forced upon us by our own highly learned medical writers.

It is time that we began to feel ashamed of this idiom, which is a mockery of science; and indeed we are beginning to despise it.

There is in the forty-sixth volume of the *Deutsche Zeitschrift für Chirurgie* an article by Ludwig Herzog, entitled *Die Perityphlitis vom chirurgischen und*

* Read before the German Medical Society of the City of New York, April 3, 1899.

internen Standpunkte beurtheilt. Another paper by the same author, entitled *Behandlung der Perityphlitis*, which appeared in the *Zeitschrift für klinische Medizin*, Bd. xxxvi, Heft 3 u. 4, gives for the affection in question no other name than perityphlitis. Thus we see that there are writers in Germany who consider the term perityphlitis good enough. Recently the *New York Medical Journal* has substituted for appendicitis "appendicular inflammation," and I am sure a more correct term can not be found. Professor Küster, of Marburg, Germany, proposes the word epityphlitis. In order to construct this word he had first to construct a new anatomical term, namely, *ἐπιτυφλόν*, something upon the typhlon. Perhaps I am mistaken, but I never heard the appendix vermiformis called by that name.

From the Latin "appendix vermiformis" no name can be formed, and the German "*Wurmfortsatzentzündung*" would not be acceptable for international use; therefore it appears commendable to adhere to the terms of our Greek colleagues: scolecoiditis, perityphlitis, and paratyphlitis.

Some time ago Dr. Gerster called attention to the name scolecoiditis as the only correct one for international use, and it is the only correct Greek name for appendicitis.

While writing these remarks I have happened to see a treatise of Dr. Robert T. Morris's on appendicitis. As I did with other colleagues, I asked him if he would kindly support me in my proposition to purge our literature of the distasteful term. He answered:

"DEAR DR. ROSE: I quite agree with you that the word 'appendicitis' is an abomination, and I published a protest against it several years ago, suggesting the word 'cephyaditis' on the authority of Galen's use of *εφφάδης* for describing the appendix vermiformis. I should have used the word 'cephyaditis' in my book upon the subject, excepting for the fact that other words—'epityphlitis,' for instance—were being advocated, and it seemed best to wait for an agreement among authorities.

Yours truly,

"ROBERT T. MORRIS."

Linguistically there can certainly be no objection against either cephyaditis or epityphlitis; moreover, the name selected by Dr. Morris is to be preferred, in so far as it is formed from a word already existing in literature to describe the appendix vermiformis.

It would be to no great purpose, and I should hardly feel justified in occupying your time, if I were to confine myself to this *εφφάδης*, this *ερεσενσεν*, appendicitis, without calling your attention to faults of our nomenclature in general. Indeed, appendicitis serves me only as a starting point. I shall not enter into linguistic discussion, but mention only a few things which may prove of interest to every one of us practising physicians.

Virchow says: "Is it not the first attribute of a man of science that he should understand how to speak the language of science? The ability of the expert shows it-

self by nothing so much as by his correct application of technical terms. Nothing will make a more favorable impression for him, by nothing will he be of better service." Virchow thus speaks on medical nomenclature—strange to say, he calls it quite inharmoniously terminology—gives the reasons why scientific names are a necessity, and condemns the mania for inventing and arbitrarily coining new names.

Hyrtl, foremost of all others, complains of the arbitrary and unprincipled language of anatomy, and regrets that we are not able to substitute better names for those which are antiquated, faulty, and nonsensical. He says further: The fact that the attempts of Dumas, Schreyer, and Chaussier were hardly noticed and were not taken seriously did not encourage labors of this kind, and the main exertions of others to introduce proper names in place of the unscientific and silly ones only served to multiply the confusion in anatomical technical terms, inducing Schreyer, Pierer, and F. C. Lorenzo to create a new science—namely, an anatomical synonymy. He complains of the fashion of coining barbaric words for insignificant anatomical observations, and expresses the desire that we might unite for the purpose of purifying and improving the anatomical vocabulary.

When we read the prefaces of the different medical dictionaries we meet everywhere this complaint about barbarisms in our nomenclature. All attempts at correction thus far—even since Hyrtl—have been futile. On the variegated, the hybrid lexicology of the German Anatomical Society I have already pronounced myself several years ago; my remarks were published in the *New York Medical Journal*, and also in my book, *Christian Greece and Living Greek*.

And after all there exists a simple way, one that should most naturally suggest itself to every one of us, a way which surely will lead to success in substituting for barbarous, corrupt, or ill-chosen words, mostly supposed to be Greek, really good Greek words, and in doing away once and for all with hybrids like appendicitis which sound half Latin, half Greek. I confine myself here to Greek because this alone, or at least principally, is to be considered.

The language spoken and written to-day by Greeks of education, especially by men of science, is as pure, as unadulterated, unmixed Greek as the Greek of the most brilliant period of the classical ages. The Greek language of to-day can be compared with virtue. As virtue, and virtue only, is her own master—not, as are all other things, subject to the influence of fortune—so is Greek, and Greek only, of all European languages, her own master. Greek of to-day needs no foreign words for its completion, and the Greeks want no foreign words in their language. They are jealous of its purity, and detest, therefore, foreign admixtures. Whoever knows the history of the Greek of to-day can testify that barbarisms or linguistic monstrosities are an impossibil-

ity in the scientific medical literature of Greece at the present time.

This may sound strange to some who have accepted the misrepresenting traditions about new Greek, who know the Greek of to-day only from hearsay. But I have brought with me the proofs, nay, the conclusive evidence, of what I have said. Here we have a book, *Einleitung in die neugriechische Grammatik*, written by a true man of science, by a prominent philologist, a Greek of Crete, Ilatzidakis, professor in the University of Athens. It is written in German, dedicated to the author's German teacher, Delbrück, of the University of Jena, and professor of philology. The book gives the history of the Greek of to-day. Here we have also the three Greek books of which I have spoken already, the Greek translation of Niemeyer, the *Anatomy* of Papaioannis, and the monograph of Zaïmis. Any one who has learned Greek in school, and has not forgotten it, will be able to read and understand these books without difficulty, and, should he need a dictionary, his Greek school lexicon will suffice. I think a more conclusive evidence for my assertion can not exist.

Medicine, the science, can not deny itself, can not deny its history, can not give up the Greek and Latin names of her technical language, by means of which the scholars of all civilized nations possess a common, simple relation to each other. In order to have the nomenclature, which has become unscientific by the introduction of barbarisms, scientific again in regard to Greek terms, we have to adopt names which are in use in Greece to-day, and we should not accept a term purporting to be Greek which can not stand the test in Greece. In my book already quoted I have given extensively reasons for this necessity.

I have addressed myself to one of the German scientific journals, I think it was the *Deutsche medizinische Wochenschrift*, asking why the perfect Greek nomenclature of to-day was not taken notice of in Germany. The answer has been that they had reasons not to enter into the subject. Here we have the nigger in the wood pile!

The errors of a prominent man, as we all know from the history of Semmelweis, are sometimes more serious in their consequences than those of everyday people. I noticed Virchow's error in his inaugural address as rector of the University of Berlin in speaking of Greek as of a dead language, and I tried to direct his attention to this error, but no attention has been paid to my letter.

None of the medical lexicographers whom I know has even mentioned with one word the existence of a contemporary Greek nomenclature. This is to me incomprehensible.

I have written to the philological collaborator of a German medical lexicon to draw his attention to various forms of nonsense in the book, some of which is very learned; he answers that he had to leave some things

which were incorrect because the medical authority of the book forced him to do so. The receipt of this answer means to me progress, and I am indeed thankful to have received it.

I may be allowed now to produce some examples to demonstrate some of the nonsense existing in our nomenclature. It is not my fault if some comical elements may intervene. There we have first of all polielinie and polyelinie, the one spelled with i, the other with y. These words have caused a great deal of dispute; it has gone so far that one of the disputants has called the other *stultus*, although both were classical scholars, and after all they were both in the wrong—the word is neither polielinie nor polyelinie, but astyelinie.

I shall not lose much time with the word vaginismus for colicospasmus, or the word vaginitis for colpitis; these condemn themselves; but there exists another class of words which, although they seem to be correct so far as language is concerned, are nevertheless unscientific, and these words we should keep an eye on. The title-page of some text-books gives us such an example when it reads "pathology and therapy." I should like to know in what way therapy is related to pathology. It should read, as it reads in the Greek text-books, "nosology and therapy." On the first page of the text-book of Niemeyer we find the word pathogenesis. Now, if we knew everything that we don't know, we might perhaps allow this word to pass, although, used in the sense in which it is intended in Niemeyer's book, it would have no sense after all. In the Greek books of to-day it reads *Γένεσις τῆς Νόσου*. Pathogenesis as a word can not be found in any Greek lexicon. Horrid is it to call the cardiac orifice of the stomach cardia, and to call gastric pains cardialgia. This reminds me of the Irishman who had bronchitis of the liver.

There exists yet another class of words which have been coined at the expense of Greek, which are miserable counterfeits, however. One of these is the word hydrophobia. Lyssa, after a symptom attributed to it by laymen, is called in German *Wasserscheu*. Some German scholar translated *Wasserscheu* into Greek, and the world's literature accepted it. You would look in vain for the word hydrophobia as a synonym for lyssa in a Greek dictionary.

Not only in the nomenclature, but also in medical books and journals, alongside of real technical terms we notice the fashion of employing *ἑλληνισμοί* words, such as polypragmasia, which I see quite frequently in most elegant and otherwise scientific German writings. It is a miserable corruption of a Greek word. All of us who are able to think in two or more languages are well aware what arrant nonsense is promulgated when somebody who, for instance, knows English only through grammar and dictionary attempts to translate from his own mother-tongue—say German—into English. Exactly the same is the case in regard to Greek, if we know only how to read and to write, but can not think in Greek

—if we do not possess the Greek *Sprachgefühl*—and this our philologists, notwithstanding their indisputable profound learning, do not possess.

While in Athens I had some conversations about medical nomenclature with several professors of the University of Athens; some of them were philologists, some were medical men. The unanimous opinion was that the errors could not be corrected and the matter finally settled until an international commission with headquarters in Athens was called together. I wrote of this to some prominent professors of classical philology in Germany, and one of them, an exceptional man, who, on account of having been living in Greece for years, is mastering living Greek, answered: "I agree with you that future barbarism will be prevented if an academy (*accademia della crusca*) is established, which, so far as my opinion is to be considered, should consist of Greeks only for the Greek words." He complains that the chemists, with their terrible new formations of word monsters, are much worse than the physicians.

Chemistry and medicine are not scientific so long as they teach something which has proved to be false, which is unscientific; and false and unscientific is the medical technical language employed by us this very day. The criticism of chemical lexicology I shall leave to the chemists.

It is positive that our nomenclature, so far as the terms which purport to be Greek are concerned, will remain in gross contradiction to science so long as malevolence and error in regard to the Greek of to-day exist among us.

ON THE USE OF THE VALERIANATES OF CREOSOTE AND GUAICOL IN THE TREATMENT OF PULMONARY TUBERCULOSIS.*

By A. B. BRIGGS, M. D.,

ASHAWAT, R. I.

THE general practitioner is at all times confronted with cases of acute and chronic tuberculosis, the treatment of which often exhausts his utmost resources. The days when the physician could prescribe cod-liver oil or the syrup of the hypophosphites and rest content while the patient passed downward and onward to the fatal termination of the case have, happily for the patient, passed; with our better understanding of the etiology and pathology of the disease gained during the past fifteen or twenty years, we have been able to make great advancement along the lines of prophylaxis, and, until some more satisfactory treatment is presented to the profession than is at present available, it is our duty to work along the line of prevention for our most solid results, rather than by the medicinal treatment.

Still, as stated above, we are all at times brought face to face with cases of consumption that require our immediate attention and treatment—patients who of necessity must remain at home; who can not take advantage of climatic treatment.

It is not the intention of the reader to present to you to-day a paper on the treatment of phthisis, but rather to call your attention to the use of creosote and some of its derivatives in the treatment of the disease.

During the past ten years or more the number of new remedies and modes of treating tuberculosis have been almost innumerable; most of them, after a fair and impartial trial by the profession, have failed and been discarded. Creosote, or some of its preparations, has been prescribed during this period perhaps oftener than any and all other drugs, and its use has become so inseparable from the treatment of pulmonary tuberculosis that by some it has been classed almost as a specific, although improperly so.

I will not weary you with an attempt to describe its mode of action in the human economy; suffice it to say, it would appear that creosote and its various preparations and esters have no specific action on the bacilli themselves, or on their toxine-producing powers, but act rather in the alimentary canal before their absorption, and after their absorption, by favoring the elimination of the toxic albumins with which they combine. Again, the drug is eliminated largely by the bronchial mucous membrane, and thus by its local action upon the bronchial mucosa, and by its stimulating effect, the resisting power of the cells is increased and its well-known power as an expectorant accounted for.

The value of creosote as a remedy in tuberculosis is conceded by all, but its administration in sufficient doses to obtain beneficial results is often defeated by the patient's inability to take and retain it in the stomach. On this account, and also on account of the physician's inability to always obtain a chemically pure drug when prescribed, compounds of creosote and its principal constituent, guaiacol, have more often been administered.

My attention was called less than a year ago to two new esters of the drug creosote—viz., creosote valerianate (eosote) and guaiacol valerianate (geosote). Since that time I have prescribed them whenever creosote or guaiacol has been indicated, and it is to their use in the treatment of tuberculosis that I wish to call your attention to-day.

I will not refer to their chemistry in this paper, as time will not admit (besides, most probably, all of you are familiar with them), but shall beg your indulgence while I relate a short history of several cases treated during the past six or eight months.

CASE I.—Miss B., aged eighteen years, American. About May 1, 1898, gave the following history: She has never been considered strong physically, although her condition since early childhood has required the attend-

* Read before the Washington County, R. I., Medical Society, January 12, 1899.

ance of a physician but a very few times. About two years ago she was taken with a severe pain over the region of the right ureter, which continued for about four hours; this was followed by a great amount of soreness and tenderness for ten days, during which period the urine at all times contained blood. There were no febrile symptoms present, nor were there any symptoms referable to the bladder. She had a number of these attacks during six or eight months, always accompanied with blood in the urine. Her weight during this period was about one hundred and ten pounds; menstruation normal, complexion pale, anemia very pronounced. Under a general tonic treatment there was satisfactory improvement, and she had no more attacks of pain or hematuria for about nine months.

In December, 1897, there was a return of the pain in right side, with bloody urine; at this attack she complained of pain after urinating, and a desire to void the urine every hour or so. From this time until about April 1, 1898, the pain in the side gave her very little trouble, but the bloody urine continued almost daily. During this period there was a continuation of the pain over the region of the bladder, most marked after urination, with constipation, loss of appetite, and increased anemia. The patient was evidently losing flesh. Examination of the urine gave the following results: Specific gravity, 1.018; reaction, acid; albumin present; no sugar. Microscopic examination showed numerous leucocytes (pus corpuscles) in every field, with, occasionally, epithelial cells from deeper layer of the bladder or ureters, some of the epithelial cells being granular. Blood-corpuscles were present. No casts or crystalline deposits were found. About this time and subsequently up to April 1, 1898, very careful and repeated examinations of the bladder with a sound failed to reveal the presence of stone. Daily washing out of the bladder with a warm solution of boric acid reduced the pain in a marked degree; the frequency of urination became less, and there appeared to be less blood and pus in the urine; but all this time the appetite remained poor, and the patient lost weight, which on April 3d had declined to eighty-five pounds.

On April 1st it was noticed that a slight cough had developed, with expectoration, and on April 13th she had a slight hemoptysis, followed by a more severe attack on the 14th. Physical examination a few days later showed marked emaciation; pulse, 100; respiration, 24; temperature, 99.5° F. There was slight catarrhal trouble, with crackling râles over the upper lobe of the right lung, with flatness at the same point; the flatness was also noticed over the lower lobe of the right lung; very marked tenderness over the region of the right kidney and along the tract of the ureter on the same side; no tenderness over the bladder. There was cough with a surprising amount of mucopurulent expectoration, which, upon microscopic examination, showed the presence of tubercle bacilli in great numbers. A few days later a microscopic examination of the urine exhibited the tubercle bacilli in that excretion also.

On April 20th, notwithstanding the undoubted inevitable fatal termination in this case, the patient was given creosote in three drop doses every six hours, always after taking food, and on the 23d the dose was increased to six drops four times a day.

May 14th, the patient reported her mind better than at any time during the past year, and food was well digested; cough was less troublesome and expectoration was diminishing in amount; there were no more attacks

the patient stated that she slept very much better; she felt stronger and walked out of doors for half an hour. The blood and pus still continued in the urine, in which the aromatic odor of the drug was very pronounced. There was much less pain accompanying micturition, and the desire to void urine was less frequent. From about this time on, the patient gradually lost ground and died on the 12th of June, of inanition.

This was undoubtedly a case primarily of tuberculous nephritis, the deposit gradually extending by way of the left ureter to the bladder, and terminating in tuberculous inflammation of the lungs, or pulmonary phthisis.

The points of interest in connection with this case are: The marked amelioration of the most prominent symptoms soon after the administration of the creosote was begun, as shown by the improvement in the cough, with decrease in amount of expectoration; a complete cessation of night sweats; a marked decrease in the nervous symptoms, and consequently increase of refreshing sleep; and the almost magical disappearance of the morbid frequency of passing urine and bladder tormina.

CASE II.—Mr. G., American, thirty-five years of age, always healthy, no consumption in family. Wife died of phthisis pulmonalis about two years ago; had noticed for six months or more before his wife's death that he had a slight cough and did not feel as well as usual. On May 1, 1898, he presented the following history: He had been sick for over two years and unable to do manual labor for the past year; there was a severe cough with profuse expectoration of a frothy mucopurulent nature; the appetite was poor, with inability to digest and assimilate food; there was constipation alternating with diarrhoea; sleep poor; urine scanty and high-colored; had lost about sixty pounds in weight during past two years. Physical examination gave a dull percussion resonance over a large part of the right chest and the upper lobe of the left lung, accompanied with crackling and moist râles over the apex of both lungs; bronchophony with bronchial breathing and increased vocal fremitus. Microscopical examination of sputum showed the presence of tubercle bacilli. Was given six drops of creosote three times a day after meals with a twentieth of a grain of nitrate of strychnine before meals and at bedtime. June 1st he reported that he felt very much better; took more food, which was better assimilated; the cough less, with amount of expectoration about the same; he went out of doors every day, and had gained five pounds in weight; temperature, 99° F.; pulse, 80; bowels moved every day. Continued treatment.

On July 10th he reported continued improvement; had gained eight pounds; cough and expectoration very much less; night sweats had stopped; he took a liberal amount of food, which was well received by the stomach; had not vomited once during the past three weeks. Treatment continued.

During August the patient had an acute otitis media purulenta of the left ear, of tuberculous nature, and in September the same condition of affairs presented on the right side, necessitating a perforation of the drum membrane of both ears, with considerable impairment of the hearing. With the exception the patient's improvement continued up to October, 1898.

CASE III.—A young man, American, twenty-one years of age, gave a history in May, 1898, of having

been in failing health since the August preceding. He has had during the past ten months five attacks of hæmoptysis, not severe, but each extending over a period of four or five days. In December he complained of poor appetite; food was received quite well, but he had a feeling of a hard lump in the stomach for two hours after each meal; there was pain in right side and back over the lower part of the lung; he was anæmic; there was cough with expectoration and night sweats. Present weight, one hundred and fifty pounds; a year ago he weighed one hundred and seventy pounds. Pulse, 90, increased to 110 a minute on full inspiration; temperature was 99° F., with evening pyrexia. Physical examination showed a marked bronchial catarrh, limited to the two lower lobes of the right lung, with a decided imperfection of the respiratory murmur at the apex of each lung, and a slight presystolic murmur over the heart. Microscopic examination of expectorated matter showed the presence of tubercle bacilli.

The patient was ordered Bland's tonic laxative pills in ten-grain doses before meals; geosote, six drops, three times a day after meals, with nourishing food and outdoor exercise. In June he reported feeling much better; food was received well; he gained three pounds in weight; the cough was better, with less expectoration. He had one slight attack of hæmoptysis that lasted for two days; night sweats with evening febrile attacks had subsided; the pulse 80, temperature normal. He was told to continue the treatment. The improvement in this case continued, and in September the Bland's pills were discontinued. An examination of the sputum in October did not show the tubercle bacilli present.

The patient continued to improve and in December had gained seventeen pounds in weight; the cough was of little or no account, expectoration nil. A physical examination showed the chest symptoms markedly improved, although the heart murmur was still present and some pain was complained of in the side. He was still taking the geosote in six-drop doses three times a day.

CASE IV.—Miss F., American, twenty-one years of age, consulted me in April last. She had always been well until some time in January last when she contracted a severe cold which left her with a cough that has continued since. In March she had an attack of hæmoptysis, which was repeated in two days. At the time I first saw her, she reported that her appetite was good, and that food was received well, but that she had been losing flesh for the preceding two months. Emaciation was not marked; pulse 110, with decided evening pyrexia and night sweats. There were cough and sore throat with hoarseness every night and during the early morning, and pain through the back and right supraclavicular region. The expectoration was of a frothy muco-pus, of limited amount, and on microscopic examination showed the presence of tubercle bacilli. Physical examination gave slight dullness over the upper lobe of the right lung. The remainder of the chest seemed normal by percussion. On auscultation the respiration was found to be weaker and wavy in the right supraclavicular region, accompanied by marked crackling râles and bronchial breathing. I ordered eosote in six-drop doses after each meal and at bedtime, together with outdoor exercise and a supporting treatment. Improvement began within ten days and continued uninterrupted. The patient continued to take the eosote until about September 1st, when it was stopped. She has remained perfectly well since, about five months,

having gained twenty pounds in weight. A physical examination made within the past six weeks failed to reveal anything abnormal about lungs.

I have at some length reported four cases of tuberculosis treated with the eosote and geosote, and in this connection wish to speak of five others that have been under treatment at the same time, or are under treatment at present. Of these five, two were incipient cases, one of the patients having fully recovered, no symptoms having returned during the past three months, and all treatment has been discontinued during that time. The other patient is at present under treatment and has shown great improvement since the eosote was first administered, about October 1, 1898. The other three were chronic cases. Two of the patients have shown marked gain, while the third has lost ground.

To recapitulate: We have eight cases, three of incipient tuberculosis and five chronic cases. Of the three acute cases, two of the patients have made, to all appearances, complete recoveries. The third, still under treatment, is fast recovering and bids fair to result in a final cure.

Of the five chronic cases, one patient has died, three have improved, and the fifth, although showing no improvement, nevertheless has received benefit from the drug, as a lessened amount of cough and expectoration, together with a decrease of night sweats and other troublesome symptoms, is proof conclusive.

All the patients in the chronic cases are still taking the valerianates, for they recognize the fact that as soon as they discontinue them they get worse, and by their continued use they are able to at least hold their own against the disease, while two of them are able to follow their vocations.

It is an acknowledged fact that no remedy or treatment thus far established or instituted has been able to cure advanced cases of tuberculosis; it is also probable that more cases of the disease have been benefited by the administration of creosote, guaiacol, or some of their preparations during the past thirty years than by all other medicines combined, and this notwithstanding the great difficulty the profession has experienced in procuring a pure article when prescribing it, and the patient's inability to take it in appreciable doses. These objections are wholly obviated when the eosote or geosote is administered, and from my experience with their use during the past year I can say that in any and every instance where creosote is indicated we are safe in prescribing the valerianates.

The esters are both easily soluble in alcohol or ether, have the nutty aromatic odor characteristic of valerianic acid, and if given in the liquid form are best administered in alcohol, combined with essence of peppermint or oil of cinnamon. Both the drugs may be procured in capsules, coated with sugar, which is perhaps the ideal form in which to administer them. The writer has often prescribed the eosote and geosote in glycerin, with the

directions to shake well and administer in milk, and has found it a very satisfactory way to exhibit the drugs to children.

From my experience in the use of geosote and cosote I would suggest the following points for your consideration:

1. The cosote or geosote may be given with advantage in all cases of pulmonary tuberculosis.

2. It is non-toxic and non-irritating. The dose is very much less than that of creosote, from three to ten drops being as much as is ever required at a dose. From ten to thirty minims daily can be given with benefit in these cases.

3. The remedy always acts as a tonic; the appetite improves, dyspeptic symptoms subside, the patient increases in weight, the cough, expectoration, night sweats, and physical symptoms improve, while the disposition to hæmoptysis seems to be entirely under control.

4. On account of their disinfectant properties, fermentative conditions in the stomach and bowels, so often present in these cases, respond very readily and favorably to their use. Tuberculous enteritis, if present, is benefited, and self-infection prevented.

5. The well-known sedative action of the valerianates is soon demonstrated after their administration, as shown by their beneficial action on the various nervous symptoms, frequently so pronounced in these cases.

Therapeutical Notes.

A Vermifuge Powder for Children.—Dr. Albert Veillard (*Journal de médecine de Paris*, April 9th) gives this prescription for the destruction of round worms and threadworms:

R Calomel 3½ grains;
Santonin 14 grain;
Powdered sugar of milk 15 grains.

M. The whole to be given in the morning, before breakfast, in a coffee-spoonful of honey, to a child about four years old.

Hæmalbumin in Chlorosis and Anæmia.—Dr. Goliner (*Deutsche Medicinal-Zeitung*) recommends hæmalbumin for the relief of chlorosis, anæmia, and gastric and intestinal catarrhs. An effective iron preparation, provided it contains nutrient material in a predigested condition, especially albuminates, whose absorption and assimilation require no tax upon the digestive system, is the treatment *par excellence*. Such a preparation of iron is found in hæmalbumin. It is a powder readily soluble in hot water or alcohol, and contains all the salts and albumins present in the blood, i.e., hæmoglobin with hæmatin, serum albumin, and paræalbumin, in the form of albuminates. Therefore, hæmalbumin closely resembles fresh blood in its composition, the fibrin alone being absent. The iron effects of the hæmatin, together with the nutritive influence of the albuminates present in this preparation, when administered

in appropriate cases, are promptly manifested. The dose of hæmalbumin is fifteen grains three times a day. —*Medical News*, April 15th.

A "Shotgun" Prescription for Constipation.—At a recent meeting of the Paris Society of Therapeutics (*Gazette hebdomadaire de médecine et de chirurgie*, April 6th) M. Bardet spoke highly of the following complex formula, laying stress on its unirritating character and the gentleness and thoroughness of its operation:

R Cassia pulp, {	each	900 grains:
Tamarind pulp, }		
Mannite	1,200 "	
Sodium phosphate	900 "	
Hydrated magnesia	1,050 "	
Senna	600 "	
Washed sulphur, each	300 "	
Jalap,		
Scammony	150 "	
"Leplandin" [Leptandrin?]	9 "	
Baptisin	3 "	
Euonymin	30 "	
Podophyllin	90 "	
Amorphous quassin	30 "	
Extract of <i>Rhamnus cathartica</i>	120 "	
Extract of <i>Rhamnus frangula</i>	30 "	
Extract of cascara	300 "	
Extract of nux vomica, {	each, 3 "	
Extract of belladonna, }		

M. From forty-five to ninety grains for a dose, to be taken in wafers.

Protargol in the Treatment of Superficial Epithelioma.—In a pamphlet entitled *De l'emploi du protargol dans le traitement des plaies, ulcères variqueux, ulcérations syphilitiques et herpétiques, épithéliomas de la face, etc.*, Dr. Philippe Valençon, of Paris, reports two cases of superficial epithelioma of the face treated with protargol, which he considers has a manifest superiority over other topical applications. Cicatrization ensued in both cases, but the author says time must elapse before they can be said to have been definitively cured.

For Infantile Colic.—The *Riforma medica* for April 27th ascribes the following to Condie:

R Extract of hyoscyamus 3 grains;
Calcined magnesia 18 "
Powdered ipecacuanha 1½ grain.

M.

Make into ten powders. One to be taken every three hours.

The Administration of Trional. Dr. Habermann (*Centralblatt für Therapie*, 1898, p. 156; *Gazette hebdomadaire de médecine et de chirurgie*, April 30th) recommends the administration of trional in Seltzer water. According to him, this mode of exhibition has as advantages ease of solubility, agreeable taste, and rapidity of action, sleep supervening in about ten minutes. There are no unpleasant after effects.

A Spray for Urticaria.—The *Settimana medica* for April 29th ascribes the following to Gauchon:

R Alcohol, {
Chloroform, } of each 150 grains;
Sulphuric ether, }
Menthol 150 "

M.

To be used with an atomizer

THE
NEW YORK MEDICAL JOURNAL.

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK F. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 20, 1899.

THE MEDICAL INSPECTION OF PUBLIC SCHOOLS.

PROBABLY there are few municipalities in the United States in which there is any medical supervision of the public schools that can be called systematic or that is even moderately efficient. In New York we now have regularly appointed medical inspectors of the schools, acting under the authority of the board of health. They form a numerous corps, and we do not doubt that their efforts, poorly paid as they are, accomplish much in preventing the spread of infectious disease. We should like to see a better-paid body of medical men engaged in this work, but we fear the time is not very close at hand when an ideal service will be in operation. The importance of such a system of inspection is forcibly pointed out by Dr. Francis Reder, of St. Louis, in the *Medical Record* for May 13th.

Incidentally, Dr. Reder treats briefly of school hygiene, and what he has to say on that subject might well be urged upon the attention of teachers and school boards. But the main purport of his article is a sketch of the work that should be done by a medical inspector of a public school if it is to be as efficient as it might be. He would have the school visited daily by the inspector, and each of the children subjected to a physical examination in the presence of the principal or a representative, but we take it that he does not mean a thorough examination of every pupil daily, for that would be wholly uncalled for and, in the case of a large school, impracticable. A daily look at them by an acute and experienced inspector would probably be sufficient. He could readily single out those whom it would be desirable to examine minutely. Doubtless it is such a course as this that Dr. Reder has in mind. Of course there should be one rigid examination of each new pupil.

Dr. Reder judiciously remarks that it would be no part of a medical inspector's function to prescribe for the children or to offer advice, except such as might have a direct bearing upon the course to be pursued from the point of view of the general welfare. He should, however, in the case of any departure from perfect health, if of an acute nature, take measures to arrive at an accurate diagnosis as soon as possible, report all suspicious cases at once to the principal, to

the board of health, and to the child's parents, and keep a record of his work, to be summarized in the form of a monthly report. It is to be hoped that Dr. Reder's article will be extensively read and well pondered, for his recommendations are of the utmost importance.

LUXURY AND HOSPITALS.

THE perusal of the annual report of a certain hospital gives rise to some reflections in regard to luxury in hospitals. It is well known that the out-patient departments of hospitals, polyclinics, etc., however necessary they may be, not only in regard to the public but also for the continuous training of the medical profession, are nevertheless a source of grave misgiving to the general practitioners in consequence of their abuse by persons who ought really to pay a medical man for their treatment.

A decent living for the average medical practitioner is only obtainable by a process of "taking the rough with the smooth." If he is only to be employed in attending serious and bedridden cases, especially when much of his practice lies among people of limited incomes, then he gets only the "rough" end, and his life will be unusually arduous and by no means adequately remunerative; for people of that class can not and do not pay adequately in their more serious diseases to make up for the little advantage that would otherwise be gained by attendance on them in their minor ailments in the out-patient departments. Deducting the very poor, who are fit subjects for gratuitous treatment in hospitals, and who in any case are only a tax upon that charitable sense of duty to humanity which probably obtains to a larger extent among the members of the medical profession than of any other, the remainder of the population may be divided into those who can "pay their way" in medical matters, save perhaps in the presence of some overwhelming calamity, and the really well-to-do and wealthy. We have seen that the more profitable portion of the physician's work among the former class is being seriously encroached on by the abuse of the out-patient departments. A perusal of the report before us suggests the reflection that among the well-to-do also the physician's interests are in danger of being sapped by the system of pay wards in hospitals. The inspection of the very admirably executed pictures of private rooms, fitted up, as it would seem, with such luxury as to suggest that they are residences in some very expensive apartment house, prompts the question as to whether the people who could afford to pay for such luxurious surroundings are fit persons to be receiving gratuitous treatment in a hospital—for we pre-

sume that the medical treatment is unremunerative so far as the physician personally is concerned. But even if it were not, even suppose the patient who could afford to take advantage of such luxurious accommodation as is depicted in this report were to pay fees to the hospital physician in attendance, is not that to place the hospital physician in a position of undue advantage against the ordinary practitioner?

It seems to us that the accommodation of pay wards in general hospitals should be confined within such limits as would attract only the many inadequately homed workers whose surroundings are such that they could not possibly receive efficient care in their homes, and from whom the expense of provision of the few really essential comforts would take away the pecuniary capacity to adequately remunerate the doctor. A much greater amount of such pay wards as would aid this class would undoubtedly be a great acquisition to the community. But we think that the existence of pay wards framed on such a luxurious scale as those shown in the report referred to, while very advantageous, even to the wealthy, on the ground that nearly all sickness is best away from the home, should not be provided in general hospitals, but should be confined to private nursing institutions, of which we should like to see a good many established, with an adequate nursing staff and adequately found, but without any staff of medical attendants, save perhaps one or two internes, attached. This would make it incumbent on the patient who is in a position to obtain such luxurious accommodation, which even in these hospitals might with advantage be graded, to retain any physician whom he might desire to employ, to take charge of his case in the usual manner. By this means, instead of being a serious menace to the medical profession, pay wards would become a valuable and welcome auxiliary thereto. The public would be benefited, and the medical profession would not be placed at a disadvantage.

We wish emphatically to say that these remarks are not intended to be a criticism upon the particular excellent institution referred to, for there are doubtless many others in the United States to which they would equally apply; but they are directed against a system, apparently on the increase, which bids fair, as it seems to us, to still further augment the already too heavy burdens, financial and otherwise, of the medical profession at large.

THE MICRO-ORGANISM OF CANCER.

THERE has been much diversity of views as to the causation of cancerous growths. On the whole, the doctrine that malignant tumors are infective, and that they

are due to a specific micro-organism, has apparently been gaining ground. A powerful impetus has lately been given to it by certain Italian investigators, notably Sanfelice, whose experiments with a blastomyces to which he has given the name of *Saccharomyces neoformans* are summarized in a most interesting manner by Dr. William Russell, of Edinburgh, in an article published in the *Lancet* for April 29th.

It seems that in 1890 Russell himself found in cancerous growths certain micro-organisms, as he regarded them, which he was inclined to look upon as sporozoa, but to which he gave the provisional name of "fuchsin bodies." They were afterward found by a number of other observers, but Russell's view that they were the specific cause of cancer was not accepted. He, however, has continued to hold it, and it must be gratifying to him to find that Sanfelice finds "fuchsin bodies" constantly formed in the growths brought about in his inoculation experiments, and regards them as an evolutionary form of his *saccharomyces*.

Sanfelice's inoculations of guinea-pigs with the *saccharomyces* resulted in general infection, with the formation of tumors consisting partly of masses of the parasite and partly of proliferation of the cells of the part. The infection spread by the lymphatics and the blood-vessels without causing inflammation. The animals usually died within a month. In mice, inoculation led to rapid infection, with great multiplication of the parasite. In white rats the process was slower. In rabbits, it produced death in only two out of twelve inoculated, but in those that died, although the parasites were fewer in number, there was more proliferation of tissue elements than in the other animals. In his experiments on dogs Sanfelice used a form of the parasite obtained by passing it through a number of dogs, inoculating them with it and recovering it from the lymphatic glands. The tumors produced showed the typical structure of adenocarcinoma, and such clinical features as retraction of the nipple were observed. Sanfelice's observations have been to a great extent confirmed by Roncoli, and it appears as if we were on the verge of general recognition of the *Saccharomyces neoformans* as the germ of cancer.

THE LIVERPOOL SCHOOL OF TROPICAL DISEASES.

We learn from the *Lancet* for April 29th that the Liverpool School of Tropical Diseases was formally opened by Lord Lister. This school took its inception in November last from the offer of Mr. Alfred L. Jones, of the West African shipping firm of Elder, Dempster, & Co., of the sum of £350 a year as an endowment. The scheme was promptly and warmly taken up, the Royal Southern Hospital and University College, Liverpool, being associated. The attendance at the inaugural din-

ner constituted a brilliant assemblage. This is the first school to be established in England for the study of the diseases peculiar to tropical countries, an idea which emanated from the advocacy of Mr. Joseph Chamberlain. The present home of the school is a floor in the Royal Southern Hospital, including a twelve-bed ward, an extensive laboratory for blood and other examinations, with the apparatus necessary. Major Ronald Ross, of the Indian Medical Service, has been appointed special lecturer, and his lectures are to be illustrated by diagrams and lantern slides with reference to cases in the ward. All the twelve beds were full, the nationalities of the patients representing China, India, the United States, Norway, Sweden, Russia, Finland, England, and Ireland; while the diseases had been variously contracted in Java, India, Brazil, Savannah, South Carolina, and Sierra Leone, Farcados, Old Calabar, Benin, and Cape Coast Castle, the last five places being on the west coast of Africa. It seems to us about time, in view of our increasing relations with tropical countries, that some steps were taken toward some similar institutions at the larger seaports in this country.

CONTEMPLATED UNION OF MEDICAL COLLEGES.

We learn from the *St. Louis Medical Gazette* for May that there is a prospect of the consolidation of the Missouri and St. Louis Medical Colleges, to which rumor adds that the Marion Sims and Beaumont Colleges of St. Louis are contemplating a similar action. We trust that these reports will prove to be true. There has been such an excessive wave of college founding in the past that a movement for reducing their number is a healthy reaction. The only conceivable advantage to any one of this multiplicity of colleges is the supply of a large number of professorial chairs for aspiring practitioners, while their general disadvantages are manifold and serious.

THE UTILIZATION OF TOWN REFUSE.

ACCORDING to the *Medical Review of Reviews* for April, Lord Kelvin and Professor Archibald Barr have made some very interesting experiments in Edinburgh, Bradford, and Oldham on the disposition of town refuse. Damp asphalt refuse containing fecal and vegetable matter was consumed without any trace of smoke, and the steam produced by the destruction of these products was used to drive electric light and other machinery, and that without the admixture of either coal or coke. Lord Kelvin's report should prove of great assistance in solving one of the most serious problems attendant upon the congregation of men together in limited areas—viz., the proper disposal of their refuse. Apparently, Lord Kelvin has found a way not only of disposing of it, but actually of doing so to advantage.

PRIMARY EPITHELIOMA OF THE UVULA AND SOFT PALATE.

PRIMARY malignant disease of the uvula and soft palate is held to be very rare, whence the observations of Mr. Lennox Browne (*Scottish Medical and Surgical Journal*, March) are of considerable interest. He reports two cases, in the first of which the growth formed a warty mass with all the characteristics of epithelioma. The tumor was removed and the patient remained well for many months, but finally died from recurrence in

the cervical glands. Microscopical examination proved the character of the growth. This patient had a bad family history, both father and mother having been subjects of malignant disease. In the second case the left anterior faucial arch was the primary seat of the disease. In this instance also, microscopical examination confirmed the correctness of the diagnosis. As Mr. Browne aptly points out, considering the number and variety of benign neoplasms found in the uvula and its neighborhood, there can be no reason why this region should be specially exempt from malignant disease, and he suggests that such a condition may not really be so uncommon as it is thought to be. It is noteworthy that in neither of Mr. Browne's cases were the cervical glands affected, as would almost certainly have been the case had the disease been an extension from the tonsil.

THE CONSUMPTION OF COFFEE IN THE UNITED STATES.

THE *Medical News* for May 13th says that the average annual consumption of coffee in the United States during the decade 1870 to 1880 was 792,000,000 pounds; in the next decade it was 1,326,000,000; while in 1898 it was 1,580,000,000. This enormous increase in the use of this stimulant the *Medical News* considers to be another indication of the high-tension life we are leading nowadays. We are not told, however, that this increase is out of proportion to the increase in the number of people to use coffee. There are a few more people in the United States in 1898 than there were between 1870 and 1880, or even between 1880 and 1890; and it might well be found on inquiry that the amount of coffee consumed by each individual is not so much in excess now of that consumed in earlier times.

A SO-CALLED "KOCH LUNG CURE" UNDER INVESTIGATION.

ACCORDING to the newspapers, the city board of health is about to inquire into the practices of a concern calling itself the Medical Council and Koch Lung Cure, which has its headquarters in New York, but appears to have branches in Chicago, Philadelphia, and Boston. The allegations against the concern are of grave violations of law. The institution is, of course, one about which the medical profession knows nothing, one with which it seems hardly possible that reputable medical men can have anything to do.

FRICTION SOUNDS AND MURMURS.

M. H. SOULIER (*Lyon médical*, April 30th), in a communication to the National Medical Society of Lyons in support of the view, which is denied by many, that pericardial friction can produce a murmur, cites the following experiment: If the palm of the left hand is placed over the left ear, and the back of the hand is rhythmically scraped with the finger nail, a friction sound will be heard. But if in place of the nail the pulp of the finger is used, moving it with sufficient rapidity, and rhythmically like the action of the heart, the resemblance between the sound produced and a double cardiac murmur will be complete. Moreover, a circular in place of a to-and-fro movement of the finger, bearing a little harder at corresponding intervals, will reproduce the sound of a continued murmur with reduplication. This experiment, M. Soulier thinks, should

convince even the most skeptical that if the pericardium is dulled and dry from any cause, not necessarily inflammatory, a murmur may be engendered thereby; from which he infers that inorganic murmurs are probably due to pericardial friction. This roughening of the membrane, he considers, may be produced by exaggerated cardiac impulse. The correctness of his experiment is easily demonstrable to each person by himself, and certainly seems to lend color to the author's opinion on this disputed point.

THE LEGAL STATUS OF FAITH-CURE PRACTICE.

It is rumored that in some way the city board of health is meditating cooperation with the county medical societies in steps to be taken to check the business of the "healers," on the ground that they are practicing medicine without a license. It seems to us perfectly feasible to enforce the law among them, and the bounden duty of the authorities to do so. At the same time, we trust that all care will be taken to avoid any semblance of persecution.

THE RÖNTGEN RAYS IN THE TREATMENT OF ECZEMA.

If the use of the Röntgen rays for diagnostic purposes is to continue to involve the danger of occasional severe results, it is some consolation to learn that their employment has been found useful in the treatment of eczema. Mr. C. Thurstan Holland, M. R. C. S., of Liverpool (*British Medical Journal*, April 29th), reports a case of chronic eczema of the back of the hand in which seven exposures of fifteen minutes each, at intervals of several days, resulted in a cure.

BLOODY SEMINAL EJACULATIONS.

It must not be hastily concluded that emissions of bloody semen are indicative of spermatoecystitis, as is pointed out by de Keersmaecker (*Centrallblatt für die Krankheiten der Harn- und Sexual-Organen*, x, 3; *Monatshefte für praktische Dermatologie*, May 1st). His investigations show that in the majority of cases the blood comes from the prostate, but in acute inflammatory conditions its origin can not generally be ascertained with precision.

TUBERCULOUS DISEASE OF THE PUBIC BONES.

At the recent congress of the German Society of Surgery (*Wiener medizinische Blätter*, April 25th) Dr. von Büniger, of Hanau, declared that we knew next to nothing about this disease, and perhaps he was right. He gave the history of a case in which, after the diagnosis had long remained obscure, the tumor broke down under characteristic tuberculous ulceration. Resection of the affected bones is the only remedy, he says, and for that operation he prefers a curved incision above the pubes. The prognosis as regards life is good, and in his case the power of walking was regained.

ITEMS.

The Surgeon-General on Camp Typhoid.—At the recent meeting of the Association of American Physicians, according to the *Medical News* for May 13th, the Surgeon-general made some very pertinent remarks when

speaking to a paper by Dr. V. C. Vaughan On Typhoid Fever among the American Soldiers in the Recent War with Spain.

Dr. Sternberg said that it was certainly discouraging that after the lessons of the civil war we should have had a repetition of camp infection by a disease that we recognized as due to filth. He had hoped for better things, and that the profession in general would more fully appreciate the dangers, and he issued a sanitary circular describing the means of avoiding such an infection. The line officers, he said, were many of them inclined to consider all talk about cleaning the camp, about flies carrying infection, etc., as a fad of the doctors, and would not recognize danger until the epidemic had occurred. He was afraid that the doctors also throughout the country did not pay as much attention as they should to the sterilization of the excretions from typhoid patients, and these were the doctors that made up our regimental surgeons. Typhoid invaded practically all the camps, even those in northern States, where the regiments never left the home camp. He could only hope that the results of this war might be impressed upon the profession, and that we might devise some way of avoiding similar disasters in the future.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 13, 1899:

DISEASES.	Week ending May 6		Week ending May 13.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	16	6	26	6
Scarlet fever.....	204	17	171	11
Cerebro-spinal meningitis.....	0	8	0	9
Measles.....	332	14	377	18
Diphtheria.....	171	28	175	26
Croup.....	1	3	12	6
Tuberculosis.....	165	192	199	161
Small pox.....	2	0	1	0
Chicken-pox.....	34	0	37	0

The Fifth District Branch of the New York State Medical Association.—The fifteenth annual meeting will be held in Brooklyn on Tuesday, May 23d, under the presidency of Dr. Joseph D. Bryant. A discussion on malignant disease will be opened by the president's address, after which the following papers will be presented: The Nature of Malignancy in Neoplasms, by Dr. Edward K. Denham; Malignancy in the Female Genito-urinary System, by Dr. L. Grant Baldwin; Remarks on Malignant Disease of the Nose and Throat, by Dr. Jonathan Wright; The Early Recognition and Management of Malignant Disease in the Digestive System, by Dr. Max Einhorn; Malignant Disease in the Male Genito-urinary System, by Dr. J. W. S. Gouley; and The Treatment of Inoperable Malignant Tumors, by Dr. William B. Coley.

The Medical Society of City Hospital Alumni, St. Louis.—At the last meeting, on Thursday evening, the 18th inst., the following papers were presented: The Report of an Operation for Strangulated Hernia complicated with Retained Testicle and Intra-abdominal Encysted Hydrocele of the Cord, by Dr. Julius Kohl; and The Importance of Careful Preparatory and After-treatment in Abdominal Surgical Cases, by Dr. A. H. Meisenbach.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, and plague were reported to the supervising surgeon-general during the week ending May 13, 1899:

Small-pox—United States.

Mobile, Ala.	May 5	2 cases.	
Washington, D. C.	May 11	No new cases.	
Jacksonville, Fla.	Apr. 29-May 6	7 cases.	
Savannah, Ga.	May 9	4 "	
Chicago, Ill.	Apr. 29-May 6	1 case.	
Evansville, Ind.	Apr. 29-May 6	9 cases.	
Emporia, Kan.	May 6	4 "	
Garnett, Kan.	May 6	1 case.	
Kansas City, Kan.	May 8	32 cases,	8 deaths.
New Orleans, La.	Apr. 29-May 6	5 "	
Shreveport, La.	May 8	1 case.	
Baltimore, Md.	Apr. 29-May 6	8 cases.	
Boston, Mass.	Apr. 29-May 6		1 death.
Benton Harbor, Mich.	Apr. 29	Present.	
Kalamazoo Township, Mich.	Apr. 29	Present.	
St. Paul, Minn.	Apr. 29	1 case.	
Cincinnati, Ohio.	Apr. 28-May 5	15 cases,	1 "
Cleveland, Ohio.	Apr. 28-May 6	16 "	
Erie, Pa.	May 2	1 case,	
Johnstown, Pa.	Apr. 29-May 6	1 "	
Steelton, Pa.	Apr. 22-29	1 "	
Providence, R. I.	May 10	1 "	(seaman).
Nashville, Tenn.	Apr. 28-May 6	1 "	
Galveston, Texas.	Apr. 22-29	5 cases.	
Galveston, Texas.	Apr. 29-May 6	7 "	
Laredo, Texas.	Apr. 15-22	3 "	1 death.
Newport News, Va.	Apr. 6-8	2 "	
Norfolk, Va.	May 5-11	20 "	
Portsmouth, Va.	May 5-11	10 "	
Spokane, Wash.	May 6	5 "	
Milwaukee, Wis.	Apr. 29-May 6	1 case.	

Small-pox—Foreign.

Antwerp, Belgium.	Apr. 15-22	4 cases,	2 deaths
Bahia, Brazil.	Apr. 8-15	2 "	1 death.
Rio de Janeiro, Brazil.	Mar. 24-31	6 "	4 deaths.
Hongkong, China.	Mar. 25-Apr. 1	4 "	1 death.
Barranquilla, Colombia.	Apr. 8-15	4 "	
Cairo, Egypt.	Apr. 15-22	15 "	4 deaths.
Athens, Greece.	Apr. 29-May 6	1 "	1 death.
Chihuahua, Mexico.	Apr. 23-30	10 "	2 deaths.
Mexico, Mexico.	Apr. 20-27	1 "	1 death.
Vera Cruz, Mexico.	Apr. 27-May 3	2 "	2 deaths.
Moscow, Russia.	Apr. 1-15	18 "	7 "
Odessa, Russia.	Apr. 15-22	6 "	1 death.
Warsaw, Russia.	Apr. 1-15		8 deaths.

Yellow Fever.

Vera Cruz, Mexico.	Apr. 21-27	2 deaths.
Vera Cruz, Mexico.	Apr. 22-May 3	10 "

Plague.

Aden, Arabia.	Apr. 7	1 case of plague on steamship <i>Caledonia</i> , from Bombay.
Hongkong, China.	Mar. 11-25	9 cases, 7 deaths.
Hongkong, China.	Mar. 25-Apr. 1	7 "
Bombay, India.	Mar. 27-Apr. 4	892 "
Calcutta, India.	Mar. 18-25	138 "

American Gynecological Society.—The twenty-fourth annual meeting will be held at Philadelphia, May 23d, 24th, and 25th. The sessions will be held in the hall of the College of Physicians, corner of Thirtieth and Locust Streets. The profession is cordially invited to attend. First day: Tuesday, May 23d, morning session at nine o'clock. Roll-call, reception of guests, etc. Address of welcome by Dr. Edward L. Duer, of Philadelphia. 1. Early Abdominal Section for Fibroid Tumors, with a Tabular List of all Operations Prior to 1865, Dr. Charles P. Noble, Philadelphia. 2. Aetiology of Non-malignant Rectal Stricture in Women, Dr. Beulen Peterson, Grand Rapids, Mich. 3. Sixty-five Consecutive Abdominal Sections without a

Death; with Clinical and Pathological Reports, Dr. Hunter Robb, Cleveland. 4. A Case of Spondylolisthesis, with Demonstration of the Pelvis, Dr. J. Whitridge Williams, Baltimore. Afternoon session at 2.30 o'clock. 5. Report of the Committee on Antistreptococic Serum in Puerperal Sepsis, Dr. William R. Pryor, New York. 6. Report of a Case of Kraurosis Vulvæ, Dr. J. Montgomery Baldy, Philadelphia. 7. Inversion of the Uterus, Dr. B. Bernard Browne, Baltimore. 8. Thrombosis following Cœliotomy in Aseptic Cases, Dr. Henry C. Coe, New York. 9. Clinical Data bearing upon Tuberculous Peritonitis, Dr. Egbert H. Grandin, New York. 10. The Avoidance of Infection following the Operation for Complete Tear of the Recto-vaginal Septum and The Localization of Obscure Pain in the Side, Dr. Howard A. Kelly, Baltimore. Second day: Wednesday, May 24th, morning session at nine o'clock. 11. Is a Sloughing Process at the Child's Navel Consistent with Asepsis in Childbed? Dr. Robert L. Dickinson, Brooklyn. 12. Surgical Treatment of Acute Puerperal Sepsis, with Special Reference to Hysterectomy, Dr. H. N. Vineberg, New York. 13. The Abuse of the Curette in Puerperal Fever, Dr. Robert A. Murray, New York. 14. Experience in the Use of Tuffier's Angiotribe in Intrapelvic Surgery, Dr. Clement Cleveland, New York. 15. The Use of Compression Forceps in Salpingo-oophorectomy and Hysterectomy, with remarks upon the Angiotribe, Dr. I. S. Stone, Washington. 16. President's address at eleven o'clock. Afternoon session at 2.30 o'clock. 17. Vaginal Cœliotomy, Dr. A. Laphorn Smith, Montreal. 18. The Treatment of Broad-ligament Cysts by Vaginal Incision and Drainage, Dr. T. J. Watkins, Chicago. 19. Surgery of the Ovaries and Tubes per Vaginal Incision, Dr. William H. Wathen, Louisville. 20. Surgery of the Ovaries, Dr. Fernand Henrotin, Chicago. 21. Remote Results of Shortening the Round Ligaments by Vaginal Section, Dr. Henry T. Byford, Chicago. 22. The Scope of Vaginal Work, Dr. J. Riddle Goffe, New York. Executive session at five o'clock. Third day: Thursday, May 25th, morning session at nine o'clock. 23. Tuberculosis of the Kidney as an Indication for Nephrectomy, Dr. Edward Reynolds, Boston. 24. Abdominal Operations for Conditions Complicating Typhoid Fever, Dr. J. Wesley Bovée, Washington. 25. Management of Surgical Injuries to the Ureters, Dr. Beverly McMonagle, San Francisco. 26. Use of Iodoform Gauze in Pelvic Disease of Women, Dr. William R. Pryor, New York. 27. Conservative Gynecology, Dr. Seth C. Gordon, Portland, Me. 28. Report of the Committee on the Use of Mammary and Thyroid Extracts in Solid Tumors of the Uterus, Dr. William E. Moseley, Baltimore. In memoriam: 1. Theophilus Parvin, M. D., Dr. William H. Parrish, Philadelphia. 2. James H. Etheridge, M. D., Dr. Fernand Henrotin, Chicago.

The American Medico-psychological Association will hold its annual meeting in New York, at the Waldorf-Astoria Hotel, on Tuesday, Wednesday, Thursday, and Friday, May 23d, 24th, 25th, and 26th, under the presidency of Dr. Henry M. Hurd, of Baltimore.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 13th inst., Dr. Huga Summa read a paper entitled Unguentum Credé and its Use in a Case of Septicæmia Post-abortion.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Pathology, on Tuesday

evening, the 16th inst., Dr. Joseph P. F. Burke reported a case of aortic aneurysm, with specimens, and Dr. Carr exhibited specimens of gallstones.

Changes of Address.—Dr. Samuel Webb Clason, to No. 1976 Madison Avenue, New York; Dr. L. Hibbe and Dr. H. C. Hibbe, to No. 31 Stuyvesant Street, New York; Dr. M. Lewinski, to No. 156 Henry Street, New York; Dr. J. E. Zipser, to No. 352 East Eighty-fifth Street, New York.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 6 to May 18, 1899:*

APPEL, DANIEL M., Major and Surgeon, is relieved from further duty and station at Fort Logan H. Roots, Arkansas.

DEWEY, FREDERICK S., Acting Assistant Surgeon, is relieved from duty at Fort Sill, Oklahoma Territory, and will proceed to Fort Sam Houston, Texas.

DONLAN, CHARLES E., Acting Assistant Surgeon, is relieved from duty at Camp Mackenzie, Augusta, Georgia, and will proceed to Lowell, Massachusetts.

FORD, JOSEPH H., First Lieutenant and Assistant Surgeon, is relieved from duty at the General Hospital, Savannah, and will proceed to San Francisco.

KEMP, FRANKLIN M., First Lieutenant and Assistant Surgeon, is relieved from further duty in the Philippine Islands and will proceed to Fort Hamilton, New York.

KILBOURNE, HENRY S., Major and Surgeon, is detailed as a member of a board appointed to meet on June 12th at the Army Building, New York, for the examination of lieutenants ordered to appear before it, with a view to transfer to the Ordnance Department.

PURVIANCE, WILLIAM E., Captain and Assistant Surgeon, is relieved from duty at the General Hospital, Fort McPherson, and will proceed to San Francisco.

STEPHENSON, WILLIAM, Captain and Assistant Surgeon, is detailed as a member of a board appointed to meet on June 12th at the Army Building, New York, for the examination of lieutenants ordered to appear before it, with a view to transfer to the Ordnance Department.

The following acting assistant surgeons are relieved from further duty at the Josiah Simpson General Hospital, Fort Monroe, Virginia: **BAKSHADT, HARRY A.**, and **WILSON, ROY A.**, who will report to the surgeon-general; and **METZGER, JOHN A.**, who will proceed to Pittsburgh.

The following acting assistant surgeons will proceed from their stations to the places indicated: **BOYD, WILLIAM J.**, from Macon, Georgia, to Pavilion, New York; **GRAVES, LEONARD K.**, to Camp Meade, and report to the commanding officer, Nineteenth Infantry, for duty, to accompany that regiment to Manila; **ORR, JOHN C.**, from Camp Mackenzie, Augusta, Georgia, to Chambersburg, Pennsylvania; **SCHAFER, JOHN S.**, from Camp Mackenzie, Augusta, to Leechburg, Pennsylvania; and **STUART, S. M. C.**, from Camp Mackenzie to Washington.

The following officers are detailed to represent the medical department of the army at the annual meeting of the American Medical Association, to be held in Columbus, Ohio, June 6th: **PORR, BENJAMIN F.**, Lieutenant Colonel and Deputy Surgeon General;

DAVIS, WILLIAM B., Major and Surgeon; and **IRELAND, MERRITT W.**, Captain and Assistant Surgeon.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending May 13, 1899:*

BLAKEMAN, R. S., Assistant Surgeon. Detached from the *Buffalo* and ordered home to await orders.

DE VALIN, C. M., Passed Assistant Surgeon. Detached from the *Brooklyn* and ordered home to await orders.

FURLONG, F. M., Assistant Surgeon. Detached from the *Scindia* and ordered to the *Independence* temporarily.

GROVE, W. B., Assistant Surgeon. Detached from the *Vicksburg* and ordered to the *Brooklyn*.

ROGERS, F., Surgeon. Detached from the *Buffalo*, directed to be examined for promotion, and ordered home to await orders.

ROSENBLEUTH, J. C., Passed Assistant Surgeon. Detached from the *Vermont* and ordered to the *Buffalo*.

WISE, J. E., Medical Inspector. Detached from the Asiatic Station and ordered to the Naval Hospital, Yokohama, Japan, for treatment; thence home to await orders.

YOUNG, L. L., Passed Assistant Surgeon. His leave of absence on account of sickness is extended two months.

Society Meetings for the Coming Week:

MONDAY, May 22d: Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, May 23d: American Medico-psychological Association (first day—New York); New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, May 24th: Medical Association of Montana (Butte); Connecticut Medical Society (first day—Hartford); North Dakota Medical Society (first day—Fargo); American Medico-psychological Association (second day); New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society.

THURSDAY, May 25th: American Gynecological Society (Philadelphia); New Hampshire Medical Society (first day—Concord); Connecticut Medical Society (second day); North Dakota Medical Society (second day); American Medico-psychological Association (third day); New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia.

FRIDAY, May 26th: New Hampshire Medical Society (second day); American Medical and Surgical Association (fourth day); New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York.

(private); Philadelphia Clinical Society; Philadelphia Laryngological Society.
SATURDAY, May 27th: New York Medical and Surgical Society (private).

Births, Marriages, and Deaths.

Married.

COCHRAN—WATTS.—In Morristown, New Jersey, on Wednesday, May 10th, Dr. Samuel Cochran, of New York, and Miss Margaret King Watts.

HOLSTEIN—HOPKINS.—In New Orleans, on Saturday, May 6th, Dr. James H. Holstein, of Harrisonburg, Louisiana, and Miss Dora A. Hopkins.

Died.

BARRETT.—In Boston, on Tuesday, May 9th, Elizabeth, infant daughter of Dr. M. J. Barrett.

MINOT.—In Milton, Massachusetts, on Thursday, May 11th, Dr. Francis Minot, of Boston, in the seventy-ninth year of his age.

TRACY.—In Saranac Lake, New York, on Thursday, April 13th, Dr. Robert S. Tracy, aged twenty-seven years.

Letters to the Editor.

THE PERIOD OF INCUBATION OF MEASLES.

FRANKFORT, N. Y., May 8, 1899.

To the Editor of the *New York Medical Journal*:

SIR: In the *Journal* of May 6th appears a letter from Sara Newcomb Merrick, M. D., upon the above-named subject. In this communication the doctor bases conclusions upon an experiment when she was employed as a teacher in the far South.

Believing that the "facts" as related are based upon error as to the source of infection in this so-called experiment, it naturally follows that the period of incubation will have to be modified. In my opinion the school did not become infected by reason of the boy who came a mile in the open air, remained in the school fifteen minutes, and came in immediate contact with no one. It is much more in keeping with experience to conclude that the infection which found forty-two little ones came from the "little sister" for whose books the boy came, "because she had the measles." We are all familiar with similar instances when the child is allowed to continue to attend school in the early stages of disease, during which time infection is communicated to many others. I believe that readers of the *Journal* will hardly accept the reported source of the infection, but, like myself, will find sufficient cause about the "little sister."

It is fortunate, too, for us all that the infections are not carried from the sick to the well to any such alarming extent as the doctor's report would indicate. If this were true the physician would be little less than a public nuisance as he delivered death-dealing infections from home to home.

In a practice of more than twenty years, having had

to do with hundreds of cases of this and other infectious diseases, I have never had the misfortune to carry into my own or other home any one of them, and I wish to protest against the theory of carrying wholesale infection in clothing under the conditions related in this outbreak of measles.

GEORGE M. MCCOMBS, M. D.

MODIFICATIONS OF THE HAGEDORN NEEDLE.

470 COMMONWEALTH AVENUE, BOSTON, April 27, 1899.

To the Editor of the *New York Medical Journal*:

SIR: In the April 15th issue of your *Journal*, on page 546, you publish under the head of New Inventions Foster's modification of the Hagedorn needle. I beg to say that this modified form of the Hagedorn needle has been in use here in Boston for the past ten years, and is kept in stock by all the principal instrument dealers here. It goes commercially under the name of Packard's needle. I have recently learned that the Kny-Scheerer Co., of New York, manufacture them in Germany and import them to this country by the gross. It possesses all the advantages which Dr. Foster has so well laid down.

HORACE PACKARD, M. D.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL.B.

(Continued from page 682.)

XIX.

RECOVERY OF COMPENSATION.

Demand.—The first step to be taken by the physician to recover compensation for services performed is to make a demand on the patient for the amount which is due. This is usually and most properly done by presenting the patient with a bill. Should this means prove ineffectual and other amicable efforts likewise fail in producing the desired result, more drastic measures would then become necessary; but before departing from peaceful methods of collection and attempting to enforce the payment of the money by legal measures, it is well to first consider whether the legal status of the creditor is such as to enable him to invoke the aid of the court.

Is Physician Legally Qualified to Practise?—Has the physician fully complied with the requirements of the law so as to be entitled to practise medicine, and, if not, what legal rights has he in the premises?

The first question is one of fact, to be determined by carefully examining the statutes of the State in which the physician practises, and learning whether or not all of the requirements are fulfilled. If a license from the State board is prescribed, has this license been obtained? And if this license must be filed with a certain county officer, has it been so filed? Should such an examination show a defect in the physician's legal right to practise, a careful examination of the law then becomes necessary to determine what rights he really has.

Rights of Unqualified Practitioners.—It has been observed that the statutes of several States expressly provide that any physician practising medicine unlaw-

fully shall not be permitted to recover for his professional services.* In the majority of the States, however, there is no express provision upon the subject, and in such States the right of the unqualified physician to collect is the subject of judicial construction.

It is a familiar rule of law that no compensation can be recovered in a court of justice for performing an act which is unlawful, or which is prohibited by statute.† Upon this principle the courts of nearly all of the States have based their decisions, and have accordingly declined to aid the physician who has failed to comply with the requirements of the law in recovering fees.‡ The supreme court of Tennessee refused to permit a physician to recover where he had not procured and filed his license before the services for which he sought to obtain payment were rendered, but had secured and filed such license before suit was brought. The court said: "Where a statute has for its manifest purpose the promotion of some object of public policy, and prohibits the carrying on of a profession, occupation, trade or business, except in compliance with the statute, a contract made in violation of such statute can not be enforced."§

In Texas the court of civil appeals held that a physician who had graduated from a medical college recognized by the American Medical Association, but who had failed to procure a certificate from the board of medical examiners and have the same recorded, should not be entitled to a judgment for fees, notwithstanding no board of medical examiners had been appointed.||

And so it has been held by an early decision in Massachusetts (1822) that a physician duly qualified by the law of another State to practise in such State shall not thereby be entitled to come within the borders of Massachusetts and recover for services rendered. The court said: "The object of the act was to guard against the evil effects to be apprehended from the practices of ignorant and unskillful practitioners. This purpose can not be completely obtained, if those of this description, if any such there be, on the borders of the commonwealth, may be permitted to practise within its limits."^

This rule must, of course, be understood as subject to the privilege since extended to regularly licensed practitioners of neighboring States to attend patients within its borders.δ

The court of appeals of the State of Missouri stands alone in holding that an unqualified practitioner of medicine is entitled to recover a fee in the absence of an express statutory provision to the contrary. The court says: "Whatever may be the rule in some States, we must consider it as well settled in this State for the present that, where a contract is not prohibited by law, and has been fully executed by the person rendering the services, he may recover their value from the person who received their benefit, though in rendering the services the person was guilty of a misdemeanor, because he

rendered them without a proper certificate or license for doing so." * From a critical examination of this statement it will appear that the court discriminates between those contracts which are *malum in se* and those which are in themselves lawful, but whose execution is restricted to persons possessing prescribed qualifications; refusing to aid in collecting in the former case, but enforcing a payment in the latter, even though the party proves himself to have committed a misdemeanor in establishing his right to recover.

This is undoubtedly the law in Missouri at the present time, but the fine-haired distinction upon which it is based dwindles in importance when compared with the forceful reasoning by which the courts of other States have arrived at the contrary conclusion.

Chief-Justice Rufin, of the supreme court of North Carolina, commenting upon this distinction, said: "The distinction between an act *malum in se* and one merely *malum prohibitum* † was never sound, and is entirely disregarded; for the law would be false to itself if it allowed a party through its tribunals to derive advantage from a contract made against the intent and express provisions of the law." ‡

The Missouri court is not content with discriminating between things *malum in se* and those *malum prohibita*, but it goes a step further and says that the practice of medicine is a thing not even *malum prohibitum* except as to those unqualified to exercise its functions; and that because it is not in itself prohibited the court ought not to refuse its aid to one who has unlawfully practised medicine, an office not in itself wrongful, and which might lawfully be exercised by another.

Notwithstanding these distinctions, the question remains clear and distinct. May one unqualified to practise medicine exercise the functions contrary to the law and recover compensation by the aid of our courts? Justice Learned, of the New York supreme court, said: "It is a settled principle that one can not recover compensation for doing an act to do which is forbidden by law and is a misdemeanor. The contrary rule would make an absurdity. It would permit one to hire another to commit a misdemeanor and would compel the payment of the contract price for doing what the law forbids." §

Justice Clopton, of the supreme court of Alabama, said: "It is too well settled in this State to require further argument, that a penalty, imposed by statute, implies a prohibition; and a contract founded on its violation is void, though not so expressly declared by statute." ||

It may be safely understood from the foregoing that the law is well settled that one practising medicine or surgery without first complying with the requirements of the statutes can not enforce the payment of his fees, whether the statutes expressly so declare or are silent upon the subject—the State of Missouri being an exception to this rule.

No Recovery for Medicines furnished. The physician being disqualified to practise can not recover for

* Such provisions exist in Georgia, Indiana, Kansas, Kentucky, Louisiana, Maryland, Michigan, Nebraska, North Carolina, Rhode Island, Vermont, Virginia, and Wisconsin.

|| *Harrison vs. Jones*, 80 Ala., 112.

services rendered, but what effect does this disqualification have upon his right to recover for medicines which he has actually furnished to the patient?

An instructive case upon this question was decided in the supreme court of New York about seventy years ago. A medical practitioner who was not licensed was called to attend a patient after other physicians were unable to benefit her. Quoting from the opinion of Chief-Justice Savage: "He (the physician) came and prescribed for the patient, and cured her by the use of two phials of medicine and a box of ointment. What the medicines were the witness knew not. She was asked the value not of the medicines simply, for her answers show that she estimated the value of the services of the (physician) as worth sixteen or eighteen dollars, because the patient was cured. The medicines at the apothecary's shop would probably have been worth only a few shillings. . . . Where the same person officiates as physician and apothecary he comes within the decision of this court that an unlicensed practitioner is incapable of suing for services rendered or medicines furnished as a physician. As the patient was cured, it is to be regretted that (the physician) was not paid; but if unlicensed pretenders to skill in diseases can recover, as in this case, the statute may become a dead letter; the country will be filled with mere quacks, peddling their nostrums, and deceiving and destroying the ignorant and credulous, the very mischief which the statute is intended to prevent. I do not say that the (physician in this case) is a mere pretender, for he cured his patient, and in honor and honesty should have been paid; but it is our duty to administer the law."* In a later case an unlicensed physician attempted to recover for medicines to which he had a patent, which he had prescribed and furnished to a patient, but the court refused to give him judgment because he was in effect "peddling his nostrums in the character of a physician, and inducing people to buy and use them in consequence of their reliance on his pretended skill." "Such practices," says the court, "the law of the State has declared to be dangerous to the public health."†

In harmony with the cases above quoted from, the supreme court of Alabama holds that the question whether the unlicensed practitioner may recover for drugs and medicines furnished depends upon whether such drugs and medicines were administered and furnished by him acting in the capacity of a physician; or whether he sold them to the patient acting in the capacity of a druggist or apothecary. If in the former capacity, he can not recover for the value of such drugs, but in the latter he should be allowed to recover.‡

In full accord with the cases considered upon this point is a recent Kansas case in which the supreme court by a process of cogent reasoning concludes that a physician who furnishes drugs to a patient does so in the capacity of a physician and not as an apothecary, and that, if he is unlicensed to practise medicine, he can not recover the value of the drugs so furnished.§

In this case Justice Green said: "Can the plaintiff recover for the medicine alone, having furnished it as an attending physician? The statute in question forbids any one from practising medicine for reward or compensation, without having the qualification prescribed

therein. The object of this law, doubtless, was to prevent unauthorized and unqualified persons from practising medicine in any of its branches. The right to practise the calling of the physician is, by this statute, taken from certain unqualified persons, and the statute should not be so construed as to give a person the privilege of exercising a right which is in violation of any of its provisions. To hold that a person who furnished medicine, as a physician, could recover compensation for the medicine so furnished or prescribed, would, in our judgment, render the statute nugatory, and any unauthorized person might prescribe for a patient and simply charge for his medicine and thus defeat the very object of the law. The practice of medicine may be said to consist in three things: First, in judging the nature, character, and symptoms of the disease; second, in determining the proper remedy for the disease; third, in giving or prescribing the application of the remedy to the disease. If the person who makes a diagnosis of a case also gives the medicine to the patient, he is, in our judgment, practising medicine within the provisions of the statute in question; and if unauthorized to practise, or is acting in violation of the provisions of the statute, he is not entitled to compensation for the medicine, which he furnishes at the time, as a physician; and the instruction of the court, which said to the jury that the plaintiff below (the physician) could recover for the medicine furnished, though he might not have been entitled to practise medicine, was erroneous."*

It therefore is safe to conclude that outside of Missouri the unlicensed physician is unable to recover through the courts either compensation for professional services rendered or the cost of medicines furnished to patients by him in the capacity of a physician; and that it will accordingly be unwise for one not legally qualified to practise medicine and surgery at the time and place of rendering professional services to resort to suit for the recovery of his fees.

(To be continued.)

Pith of Current Literature.

Citric Acid in the Treatment of Ozæna.—Dr. Hamm, of Brunswick (*Münchener medicinische Wochenschrift*, 1899, No. 15; *Deutsche Medicinal-Zeitung*, April 20th), recommends the removal of the pus and crusts every morning, and the insufflation with a powder-blower three times a day of a mixture of equal parts of citric acid and sugar of milk.

The Responsibility of Alcoholized Persons.—The *Alienist and Neurologist* for April states that in a discussion at the late meeting of the British Medical Association Dr. John F. Sutherland, commissioner of lunacy for Scotland, said: "A person intoxicated can not and does not know the nature and quality of the act, or that it was a wrong act, because intoxication is insanity of the most perfect type, no matter how transient."

This statement the editor considers rather too strong, and makes the following pertinent and indisputable comment: "To constitute insanity, the change of charac-

ter from alcohol must appear as in other forms of mental alienation. If a man is intoxicated to the degree that he is insane, and that result depends much upon the man and his inherent but latent psychical instability, then, of course, he is entitled to the extenuation of mental disease. But some men can never become so drunk as not to know what they are doing and saying, nor too drunk to remember their words and acts. The man insane from drink remembers hazily, if at all, and does not realize the nature and quality of his acts as when sober. But all men drunk are not insane. Many men drunk appreciate their condition and act accordingly. Realizing the mental incubus of drink, many men under its influence prudently retire for seclusion and sleep, thus acting most rationally under the embarrassing mental burden of alcohol."

The Clinical Significance of Oxaluria.—Dr. Robert F. Williams (*Medical Register*, April 15th) records cases of oxaluria from a consideration of which he makes the following deductions: 1. Whereas the appearance of oxalates in the urine—excluding their ingestion in foods—is due to a derangement of digestion or metabolism, this derangement probably has its cause in many cases in functional nervous irregularity, which may or may not be so great as to produce general nervous symptoms; and, if these are present, they are not necessarily caused by the oxalates. 2. The condition causing the appearance of oxalates in the urine may produce symptoms closely simulating the constitutional symptoms of Bright's disease. 3. The excretion of oxalates by the kidney for a short while may occasion no local disturbance of that organ, but if continued may, by irritation, cause the appearance of albumin and casts with lessened urine, corresponding to the urinary symptoms of Bright's disease, and, if unchecked, may lead to permanent destruction of kidney tissue and to true Bright's disease. 4. In all suspicious cases in which the nephritic symptoms are accompanied by the appearance of oxalates in quantity, diagnosis should be held in abeyance and the oxaluria be overcome by appropriate remedies to exclude this as a possible cause of the symptoms before making a positive diagnosis and pronouncing a necessarily hope-dispelling prognosis.

For Blennorrhagic Epididymitis.—According to the *Indépendance médicale* for May 3d, Janowski, of Prague, recommends that the scrotum be cleansed with soap, and the following ointment applied on a layer of cotton supported by a suspensory bandage.

B. Guaiacol	45 grains;
Vaseline	450 "

M.

Oxyurides and the Vermiform Appendix.—Dr. George F. Still (*British Medical Journal*, April 1st), as the result of a series of observations published in that journal, arrives at the following conclusions: 1. That the appendix vermiformis is a common habitat of *Oxyuris vermicularis* in childhood. 2. That the generally accepted view that every single ovum of *Oxyuris vermicularis* must be swallowed before it can be hatched is at least open to doubt, and there is a strong probability that the appendix vermiformis serves in some cases as a breeding place for threadworms. 3. That the presence of threadworms in the appendix may cause a catarrhal condition therein, as shown post mortem by a swollen appearance, due to thickening of its wall. 4. That this swollen condition of the appendix due to

threadworms is associated in some cases with pain in the right iliac fossa which may simulate ordinary appendicitis. 5. That in the treatment of threadworms large injections must be used, and in view of the difficulty of dislodging the worms from the appendix, and their possible presence in the small intestine, the injections should be combined with the administration of drugs by the mouth.

Influence of Pregnancy on Ovarian Cysts.—Gottschalk (*Frauenarzt*, November, 1898; *University Medical Magazine*, May) reports the case of a patient, aged forty years, who had an ovarian cyst which two surgeons had declined to remove. She passed through pregnancy and labor normally, but on the second day after delivery developed symptoms of peritonitis, which subsided in the course of a fortnight. Nine weeks later she had a more severe attack, and abdominal section was performed successfully. The cyst was firmly adherent to the intestines, the pedicle was twisted twice around its axis, and the sac was filled with pus and foul-smelling gas. A pelvic abscess further complicated the case. Cultures of the colon bacillus were obtained from the cyst contents. The writer's deductions are that extensive adhesions may develop during pregnancy as well as after delivery. Torsion of the pedicle may follow the emptying of the gravid uterus in consequence of the sudden change in the intra-abdominal pressure. Infection of the cyst during the puerperium is well known, Zetter having reported twenty-one cases.

Communicated Madness.—The *Medical Review of Reviews* for April says that a strange story of communicated madness is reported from Ireland. Of three sisters belonging to Glencollins, near Kingwilliamstown, County Cork, one, on being married, went to live at Guinequilla, County Kerry; another settled down at Cordal, Castle-Island; the third remaining at home. Some time ago, the sister residing at Guinequilla developed symptoms of mental derangement. On hearing of this, her sister from Cordal went to visit her, and shortly afterward she also became similarly afflicted. The third sister at Glencollins, on learning of the unhappy circumstance, immediately went to see her sisters, when she, too, lost her reason. The sister first attacked has been conveyed to the Killarney District Lunatic Asylum, and it is reported that the other two are making satisfactory progress toward recovery.

Differences between Primary and Secondary Pneumonias.—Dr. Gordon W. Mylks (*Kingston Medical Quarterly*, April) thus sums up a paper read before the Kingston Medical and Surgical Society: Pneumonia may be secondary to typhoid fever, septicaemia, influenza, typhus fever, and prolonged renal disease. The points of difference, clinically, between primary and secondary pneumonias, some of which are illustrated by the cases related, are: 1. The insidious onset of secondary pneumonias, unlike the very abrupt onset of the primary form. 2. Secondary forms are more dangerous to the life of a patient. 3. The initial rigor is frequently absent. 4. The temperature rises gradually and does not go so high as in primary acute pneumonia. 5. Pleuritic extension and its never-varying sign—severe pain in the side—is often absent in secondary pneumonias. 6. Cough is very frequently absent. 7. There is usually greater disturbance of the skin and renal functions in secondary pneumonias. 8. Herpes also is usually absent.

Proceedings of Societies.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of February 1, 1899.

The President, Dr. S. ALEXANDER, in the Chair.

(Concluded from page 650.)

Nephritis complicating Acute and Subacute Gastro-enteritis in Infants and Young Children.—Dr. HENRY KOPLIK presented the paper of the evening with this title.

Dr. WINTERS said that this paper recalled to mind some work that had been done in this line by English physicians some fifteen years ago. During these investigations, the kidneys, in cases of fatal gastro-enteritis, had been submitted to Dr. Klein for microscopical examination, and nephritis had been found in every instance. This nephritis was of the same type as that found in scarlatina—namely, glomerulo-nephritis, with blood and epithelial and hyaline casts in the convoluted tubules, and was probably of infectious origin, as it was in scarlatina.

In a large proportion of the fatal cases of gastro-enteritis there were convulsions before death, and they were probably of renal origin, for they were not seen at the outset, or during the early stages of the disease, as they would be if they were due to the original infection; but they occurred toward the end of the complaint, or at the time, or after the onset of the renal complication. Investigations were made in several hundred fatal cases of gastro-enteritis, and convulsions occurred in almost every case. Not only was the renal complication of infectious origin, but in all probability all the complications in cases of gastro-enteritis were of similar nature—namely, the pneumonic process, which was formerly called hypostatic pneumonia, the pleuritic complication, frequently ending in empyema, and the meningitis, which was often a fatal complication toward the end of the disease. The thrombi formed in the lateral sinuses in the fatal cases were also of a similar nature, and not due to failure of the circulation, as was formerly supposed. He believed the meningitis and the thrombosis of the sinuses to be of streptococcus origin. In fact, if one would watch closely and compare carefully, one was impressed with the fact that virulent cases of scarlatina and virulent cases of acute gastro-enteritis in infants were very similar in their onset, in their symptomatology, in their complications, and in their modes of termination. Aside from the throat and skin lesions, there were no two diseases which resembled each other more closely.

He had only the highest commendation for the author's suggestions as to treatment. It was well understood that opium was seldom used in the treatment of acute gastro-enteritis in infants. He did not recall a single instance in cases which had been seen in consultation for several years where opium had been used by the attending physician. As so-called antiseptic drugs were useless in the gastro-enteric tract, we were forced to have recourse to the only method known of clearing this tract thoroughly—namely, by irrigation. After the first thorough washing he believed in the free use of very hot water in small quantities, given by mouth. For a period of twenty-four hours it seemed to him harmful to use either milk, beef juice, barley water, or any other nutriment.

Dr. J. H. HUDDLESTON said that he was very glad to respond to the opinions expressed in the paper and by Dr. Winters. He had been impressed by his own examinations with the frequency of albumin in this class of cases, and especially at the number of patients who appeared at the dispensaries with that condition. He had never used the adult's tube in irrigation of the infantile bowel, and had been much interested in its recommendation. He was surprised that the writer of the paper had condemned the ordinary catheter.

Dr. N. E. BRILL said he was delighted with the paper of Dr. Koplik, as it called renewed attention to the importance of bowel irrigation in the gastro-enteritis of children. He wished to state that it did not seem to him that Dr. Koplik had proved the position taken in his paper, for it was a well-known fact, which nearly every text-book presented, that the occurrence of albumin and the presence of casts in the urine need not necessarily indicate that they were the result of acute nephritis. What Dr. Koplik had proved was that there were a number of varieties of gastro-enteritis occurring in children.

As to the question of the fatality of streptococcus enteritis, it seemed to him that there were not sufficient data to base any deductions on. If he remembered correctly, having read the papers of Dr. Hirsch and Dr. Libman, who studied this subject in Escherich's clinic, those gentlemen had reported but three cases—namely, Dr. Hirsch one and Dr. Libman two. Of the patients, Dr. Hirsch's had died, and one of Dr. Libman's had died and one recovered. Dr. Libman certainly did not state that this form of gastro-enteritis was extremely fatal. It was possible that nephritis might complicate this form of gastro-enteritis, but it was probable that the pathological process occurring in these, as in the other forms, was a parenchymatous degeneration of the kidney, and not an acute inflammatory condition. This would be in harmony with the known facts that acute parenchymatous degeneration of the kidneys occurred, as a rule, in the infectious diseases, and not acute nephritis, excepting in diseases like scarlatina, yellow fever, and the like. All the preceding speakers as well had apparently forgotten this. One was not justified in concluding that there was an acute nephritis present because the patient presented oedema and the urine contained albumin and casts, for the oedema might be the result of the cardiac changes and weakness due to a debilitating disease, such as gastro-enteritis was, and the albumin and casts be the result of non-inflammatory parenchymatous changes in the kidneys.

He wished to add his tribute of praise to Dr. Koplik for deprecating the use of irritant drugs in the treatment of these bowel affections.

The President said he had listened with great interest to the paper read by Dr. Koplik. He did not agree with Dr. Brill on the question of nephritis. The microscopical findings showed blood and pus and not the indications of parenchymatous degeneration.

Then the report of pathological findings convinced him that Dr. Koplik's point was right. As to the treatment, he thought that by the use of injections of saline solutions many patients could be saved. He knew this was true in surgical cases, and he had been able to save patients that had passed into what had seemed a fatal uræmia after an operation.

Dr. R. J. CARLISLE asked, Why use subcutaneous injections instead of injections by rectum?

Dr. KOPLIK said he still felt free to call this acute

nephritis. It was like nephritis; the epithelium of the tubules of the kidney was destroyed. In scarlatina there was a piling up or desquamation and degeneration, according to Delafield. These cases might be placed in a special class until more facts were obtained.

Any albuminuria in gastro-enteritis was abnormal, and if we looked closely casts would be found. He thought that most authors agreed with him that albumin was indicative of nephritis.

The speaker said he had stated nothing new as to the treatment of these cases, for the method suggested had been used long before there was any knowledge of bacteriology, and his reason for presenting it was that he wished to emphasize its value. The reason he used the large tube was that he could get it up to the second curve of the sigmoid flexure, and a soft catheter would strike against the sacrum and could not be passed as high and as readily. The large-sized tube was easy to pass and the water could be introduced quicker.

His reason for using hypodermoclysis was that in desperate cases we should use every means available.

Book Notices.

The Influence of Character and Right Judgment in Medicine. The Harveian Oration delivered before the Royal College of Physicians, October 18, 1898. By Sir DYCE DUCKWORTH, M. D., LL. D., Hon. Fellow of the Royal College of Physicians of Ireland, etc. London, New York, and Bombay: Longmans, Green, & Co., 1898. Pp. 7 to 53.

THE task laid upon the Harveian orator is indeed not a gentle one, for he must traverse ground already covered many times and by some of the most famous of those who are able to combine medicine and oratory. Our author apologizes for the worn nature of the topics assigned, then plunges in bravely and sketches the lives of some of the famous benefactors, financial and scientific, of the Royal College of Physicians. From this he turns to the great field of modern science, and touches on the work yet to be done concerning the relation between the patient and the bacterium. He says we should not be satisfied with the mere discovery of the organism, but endeavor to determine the conditions which permit it to enter and attack the apparently healthy body. He then speaks of gout and serofula as fields not yet cleared up, and finally refers to that great experiment now being tried in England, the abolition of compulsory vaccination. The oration closes with a plea for the wider recognition of the moral force which guided Harvey, the desire for truth.

The Principles of Bacteriology. By Dr. FERDINAND HUEPPE, Professor of Hygiene in the University of Prague. Authorized Translation from the German by Dr. E. O. JORDAN, Assistant Professor of Bacteriology in the University of Chicago. Chicago: The Open Court Publishing Company, 1899. Pp. x, 167. [Price, \$1.75.]

THE scholarly character of this work was fully set forth in the review of the original German edition, which appeared in this journal in 1896. Of the treatise itself it may now be said, after three years, that its many excellent features have been universally recognized, and that it stands as a classic in the literature on bacterio-

logical principles. Possibly the author's intolerance of opposing views may appear to many as disagreeably blunt, now that the polemical discussions appear in plain English, and it must be admitted that our increased knowledge of some subjects now permits of more accurate statements on some points in descriptive bacteriology than were advisable in 1895. Yet, in its main features, the work still leaves little to be desired in this department. While the German text was unusually difficult, the work of the translator, Dr. Jordan, is highly commendable, the usual remnants of German idiom being almost entirely absent, although the full meaning of the author has been very uniformly retained in good English.

The publishers, also, may be congratulated on the general appearance of the book. On many grounds, therefore, the work deserves a place in every bacteriological library.

L'Exercice de la médecine et le charlatanisme. Par P. BROUARDEL, Professeur de médecine légale et doyen de la Faculté de médecine de l'Université de Paris, etc. Paris: J.-B. Baillière et fils, 1899. Pp. viii-560. [Prix, 12 fr.]

THIS interesting course of lectures treats of a subject to which but little attention is directed in medical education in this country. Perhaps this is partly due to the fact that the sanitary laws vary greatly in the different States, but nevertheless too little instruction is given at present on the medico-legal side of medicine. Brouardel has endeavored to present those points at which, so to speak, the medical practitioner comes in contact with the law. The first part of the book concerns the conditions under which a person may legally practise medicine in France, and this is of special interest to the American student, for it covers the laws governing the admission of foreign students to the French universities and their right to practise after obtaining a degree. There are explanations of the conditions of notification of contagious diseases, of expert testimony, and of the responsibility in the use of powerful drugs; there is also a discussion on fees, from which it would appear that our French brethren have difficulties in the collection of the same; and, finally, there is a chapter devoted to the question of illegal practice and charlatanism.

The Microscopy of Drinking Water. By GEORGE CHANDLER WHITPLE, Biologist and Director of Mount Prospect Laboratory, etc. First Edition. First Thousand. New York: John Wiley & Sons, 1899. Pp. xii-300.

WHILE the importance of the chemical and bacteriological analysis of water has long been recognized, the study of the lower forms of animal life included under the term "microscopy of water" has received far too scant attention as a branch of hygiene. It is beginning to appear that quite as accurate estimates of the purity of drinking water may be based upon its microscopy as upon the somewhat uncertain and more laborious results of chemical and bacteriological analysis. On this account the appearance of an elementary work upon the forms of animal life commonly found in drinking water, and the significance attaching to their presence, is most acceptable to a large class of reader who are brought in contact with this subject. The present volume is specially adapted to the needs of the medical profession, as the practical use of the data presented requires only a moderate biochemical training. The first half of the

work contains a great deal of useful information regarding the objects and methods of microscopical examination of water, the factors governing the appearance of micro-organisms in water, the origin and significance of odors in water, and the method of storing surface water. The remaining chapters are devoted to an elementary description of the principal genera of micro-organisms, beautifully illustrated by twenty-nine full-page, half-tone pictures. The volume will fully repay careful reading, is sufficiently complete for an elementary book of reference, and should find a place in every medical library.

On Varix: Its Causes and Treatment, with Especial Reference to Thrombosis. An Address delivered at the Inaugural Meeting of the Nottingham Medico-Chirurgical Society, Session 1898-1899. By WILLIAM H. BENNETT, F. R. C. S. Eng., Surgeon to St. George's Hospital and Joint Lecturer on Surgery in the Medical School, etc. Reprinted from the *Lancet*, October 15, 1898, with the Addition of Twelve Illustrations. London, New York, and Bombay: Longmans, Green, & Co., 1898. Pp. 53.

THIS small volume contains an excellent discussion of the subject of varicose veins, special attention being directed to the more dangerous accidents which may occur in those afflicted with this malady. These are the rupture or laceration of a large varix and the formation of a thrombus in the lumen of the diseased vein, with the attendant danger of severe or fatal embolism. The various methods of treatment are carefully considered, and a number of interesting illustrative cases are included from the author's practice. The book is well bound and printed.

La Photothérapie. Par N. R. FINSEN, I. Les rayons chimiques et la variole. II. La lumière comme agent d'excitabilité. III. Traitement du lupus vulgaire par les rayons chimiques concentrés. Publication du *Finsen's medicinske Lysanstalt de Copenhague*. Paris: Georges Carré et C. Naud, 1899. Pp. vi-7 to 99.

THE study of the therapeutic effects of light upon the organism may be said to begin at a very early date, for we know from the Latin writers that the Romans were accustomed to take a sun bath as a part of their regular regimen. The advantage gained by this process must have been in the increased perspiration and the stimulus given to the peripheral circulation by the heat and chemical action of the sun's rays. Finsen has approached the problem from a different standpoint. He has studied the harmful effects produced, and finds that they are caused not so much by the light rays as by those invisible chemical rays, the so-called ultra-violet. Acting on the idea that these rays were injurious in any acute inflammation of the skin, because they caused additional irritation, he experimented with small-pox, and, excluding all chemical rays by a deep red glass, found that the course of healing was much lightened. The vesicles did not suppurate and the pitting was very slight. These results have been verified by a considerable number of other observers, and their reports are collected in the form of an appendix at the end of the pamphlet. Use has also been found for these chemical rays in the treatment of lupus by concentrating upon the diseased area either sunlight or the electric-arc light which have had the heat rays removed. This is accom-

plished by passing the light through a hollow lens which has been filled with cupric-ammoniosulphate solution. The results of this method are too recent to permit any conclusions to be drawn at present.

Suite de monographies cliniques sur les questions nouvelles en médecine, en chirurgie, en biologie. No. 14. Traitement de la syphilis. Par E. GAUCHER, Professeur agrégé à la Faculté de médecine de Paris, etc. Pp. 36. Paris: Masson et Cie., 1899. [Chaque monographie séparément 1 fr. 25.]

THIS is a record of the personal views of the author on the treatment, and is accordingly clear and practical. He divides treatment according to the stage of the disease. The primary lesion, in his opinion, should not be excised, for the disease has invaded the system before the appearance of the chancre. Only in case of acute secondary infections of the diseased area is there to be any active local treatment. Treatment of the general disease should begin as soon as a diagnosis can be made, without waiting for the appearance of secondary eruptions, since it renders the latter milder in their manifestations. Mercury bichloride is the best preparation for administration by the mouth, and that route should always be chosen if possible. Inunctions are uncertain and the hypodermic methods are painful and dangerous. Calomel should not be used in injections, but one of the soluble salts, preferably the benzoate of mercury, should be employed. The iodides are useful adjuvants in the first stage of the disease and curative in the tertiary. The treatment should be continued at least four years. Many other suggestions and useful formulæ are contained in this little monograph, but enough has been given to show its scope.

A Practical Treatise on Fractures and Dislocations. By LEWIS A. STIMSON, B. A., M. D., Professor of Surgery in Cornell University Medical College, etc. With Three Hundred and Twenty-six Illustrations and Twenty Plates in Monotint. New York and Philadelphia: Lea Brothers & Co., 1899. Pp. xix-19 to 818. [Price, \$5.]

THE new edition of this most valuable book is especially welcome in consequence of the much greater attention now being devoted to the minute study of bone injuries because of Röntgen's discovery, and also owing to the changes which have taken place in the methods of treatment of fractures, as regards both splinting and the operative replacement of complicated fractures and dislocations. The work now appears in a single volume, a much more convenient form than the two volumes previously published, and there have been many changes in the text to correspond with the author's increased experience and the alteration of opinions regarding the mechanism and nature of some obscure forms. The most marked instance of these changes is in the discarding of the old classification of "fractures of the base" and "fractures of the vault" of the skull, and the substitution of "circumscribed fractures of the vault" and "fissured fractures with injury of the brain," a change which places the emphasis on the more important lesion, the injury to the cerebral structures. We notice with some interest the very conservative attitude toward the final diagnostic value of the Röntgen rays, the author holding that except in very complicated cases of fracture near a joint the use of the rays furnishes very little more information than that afforded by the careful use of eyes

and fingers, and that great care is necessary in the interpretation of the pictures obtained. Whether this voices the general opinion of surgeons at the present time is rather doubtful, but certainly too much reliance is often placed on an imperfect plate when the case requires nothing but careful palpation for a diagnosis.

The American Yearbook of Medicine and Surgery. Being a Yearly Digest of Scientific Progress and Authoritative Opinion in all Branches of Medicine and Surgery, drawn from Journals, Monographs, and Text-books of the Leading American and Foreign Authors and Investigators. Collected and arranged with Critical Editorial Comments by SAMUEL W. ABBOTT, M. D., JOHN J. ABEL, M. D., J. M. BALDY, M. D., CHARLES H. BURNETT, M. D., J. CHALMERS DA COSTA, M. D., W. A. NEWMAN DORLAND, M. D., LOUIS A. DUBRING, M. D., D. L. EDSALL, M. D., VIRGIL P. GIBNEY, M. D., HENRY A. GRIFFIN, M. D., JOHN GUTIÉRAS, M. D., C. A. HAMANN, M. D., ALFRED HAND, JR., M. D., HOWARD F. HANSELL, M. D., MILTON B. HARTZELL, M. D., BARTON COOKE HURST, M. D., E. FLETCHER INGALLS, M. D., WYATT JOHNSTON, M. D., W. W. KEEN, M. D., HENRY G. OHLS, M. D., WENDELL REBER, M. D., DAVID RIEMAN, M. D., LOUIS STARR, M. D., ALFRED STENGEL, M. D., G. N. STEWART, M. D., J. R. TILLINGHAST, JR., M. D., and J. HILTON WATERMAN, M. D., under the General Editorial Charge of GEORGE M. GOULD, M. D. Illustrated. Philadelphia: W. B. Saunders, 1899. Pp. 4 to 1102. [Price, \$6.50.]

THIS useful work presents the same claims to consideration as in previous years. The list of contributors is almost unchanged with the exception of the serious loss sustained through the death of Dr. Pepper.

Such books are, by their nature, precluded from showing to any marked extent the individuality of the editors, yet there is a considerable difference in the methods shown in the different articles. To a great extent a wise conservatism is apparent, and much matter of doubtful or ephemeral value is commented upon by the editors with dissent or protest. It is, of course, impossible to determine each year how much of its literature will be forgotten before the close of the following year, but it is probable that "the results of the advances made in all departments of medical science," as the editor in chief puts it, may be contained in a smaller space than the eleven hundred pages of the *Yearbook*. We would not protest against yearly reviews; they have become indispensable, and the one under consideration is one of the best as well as the bulkiest, but unquestionably the modern tendency to superficial and desultory reading, and all that it entails, is encouraged by their use.

To review the book in detail is out of the question, but a glance at the different subjects shows their general excellence.

In connection with the recent agitation of the subject, the statement that living streptococci have been found in so-called anti-streptococci serum, as well as tubercle bacilli in the tuberculin R of Koch, is startling, and indicates the danger of using preparation of unknown composition in the serum treatment.

The article on surgery is a model of its kind, regards both material and editorial comments, and the same may be said of other portions of the work.

If more discrimination could be shown and the bulk of the book reduced by the elimination of worthless matter, and not by too great condensation, a tendency to which is noticeable, and which leads to a cataloguing of progress rather than a review, this *Yearbook* would remain among the best of its kind.

International Clinics. A Quarterly of Clinical Lectures on Medicine, Neurology, Surgery, Gynecology, Obstetrics, Ophthalmology, Laryngology, Pharyngology, Rhinology, Otology, and Dermatology, and Specially Prepared Articles on Treatment and Drugs. By Professors and Lecturers in the Leading Medical Colleges of the United States, Germany, Austria, France, Great Britain, and Canada. Edited by JUSTIN DALAND, M. D. (Univ. of Penna.), Philadelphia, Instructor in Clinical Medicine and Lecturer on Physical Diagnosis in the University of Pennsylvania, etc.; J. MITCHELL BRUCE, M. D., F. R. C. P., London, England, Physician to and Lecturer on the Principles and Practice of Medicine in the Charing Cross Hospital; and DAVID W. FINLAY, M. D., F. R. C. P., Aberdeen, Scotland, Professor of the Practice of Medicine in the University of Aberdeen, etc. Volume IV. Eighth Series, 1899. Philadelphia: J. B. Lippincott Company, 1899. Pp. xii-375.

THE most striking feature of this volume is the number and excellent quality of its illustrations. There are no fewer than twenty-two plates and drawings, exclusive of figures and charts, greatly enhancing the clearness and value of the articles with which they are inserted. In other respects also the current issue is a worthy successor to previous volumes. The lectures of Professor Grancher on tuberculosis are continued, and a series by Rosenheim on the treatment of chronic constipation is begun. The latter are upon a subject that is of more than common interest, and the thoroughly practical character of the first lecture leads us to look forward with impatience to those that are to follow. Among other very practical articles are one by McGillivray on corneal ulceration, one by Hale White on alterations of weight by diet, and a report on Trendelenburg's operation for varicose veins by Gould. Martin reports a case of pernicious anemia in which recovery took place—certainly a most unusual outcome.

Surgical Nursing. By BERTHA M. VOSWINKEL, Late Nurse-in-Charge of the Children's Hospital, Columbus, Ohio. Second Edition, revised and enlarged. With One Hundred and Twelve Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. xvi-11 to 206. [Price, \$1.]

THIS small volume on surgical nursing seems to present the essentials of the subject quite as fully as is necessary. It is abundantly illustrated and the printing and binding are above the average.

Handbook of Obstetric Nursing for Nurses, Students, and Mothers. Comprising the Course of Instruction in Obstetric Nursing given to the Pupils of the Training School for Nurses connected with the Woman's Hospital of Philadelphia. By ANNA M. FELLERTON, M. D., Obstetrician, Gynecologist, and Surgeon to the Woman's Hospital of Philadelphia,

etc. Fifth Revised Edition, illustrated. Philadelphia: P. Blakiston, Son, & Co., 1899. Pp. xiv-17 to 262. [Price, \$1.]

THE publication of a fifth edition of this book on obstetric nursing furnishes some evidence of its popularity and value. It is simply and clearly written and well illustrated. It is a work which should be read by every one interested in the subject.

New Inventions, etc.

A SIMPLE INHALER FOR THE COMBINED ADMINISTRATION OF GAS AND ETHER.

By CHARLES H. PECK, M. D.,
ATTENDING SURGEON TO THE FRENCH HOSPITAL.

THE advantages of beginning ether anaesthesia with nitrous-oxide gas have long been known, but interest in the method and its practical revival for routine work in most of the larger hospitals in New York is of comparatively recent date, and is due chiefly to the efforts and able demonstrations of Bennett. Few anaesthetists can hope to rival the skill of Dr. Bennett in the use of this method, which in the hands of an expert is certainly the ideal general anaesthesia for the great majority of cases, but any hospital junior can be taught to give it sufficiently well for all practical purposes, provided a suitable inhaler not too complicated is available.

In most of the hospitals the gas is first given with one of the ordinary inhalers made for dental practice, and then, when the patient is thoroughly under the influence of the gas, ether is quickly substituted (preferably given in one of the closed ether inhalers, such as the Ormsby) and rapidly pushed, allowing very little admixture with air until ether anaesthesia replaces that of the gas. The transfer from gas to ether in this manner is attended with some difficulty, and requires a considerable amount of skill; the patient may partly recover consciousness and struggle before the ether begins to take effect, or the abrupt change to strong ether vapor may cause temporary cessation of breathing, with the attendant cyanosis of asphyxia added to the normal cyanosis of gas anaesthesia. The advantages of an inhaler with which the change from gas to ether can be made gradually are self-evident. The facts that no such inhalers are manufactured in this country and that those obtainable abroad are complicated and expensive have led me to devise a modification of one of the simple gas inhalers that would meet the indications and be easily manipulated.

The accompanying cuts show the inhaler, which has been in use regularly in my service at the French Hospital, and also in private work, since July, 1898.

The inhaler is attached to a cylinder of gas with the ordinary tube and bag. A sponge is saturated with ether and placed in the ether cup. When the reservoir is being filled with gas and the inhaler is first applied to the face, the cut-off *c* is thrown forward, preventing the escape of gas, and the patient is allowed to breathe air, which enters through the opening *e* for a moment. After a few inspirations, when the patient has gained confidence and is breathing deeply, cut-off *c* is thrown sharply back and pure gas is given until the patient is thoroughly under its influence. Up to this time cut-off *d* remains thrown backward as in Fig. 1, preventing the entrance of ether vapor and allowing the free passage of gas. When the patient is thoroughly under the gas, cut-

off *d* is thrown about a third of the distance forward, the gas has been completely shut off, and the amount allowing the admission of a little ether vapor, and clos- can be regulated as desired. The whole inhaler can be

FIG. 1.—*a*, ether cup; *b*, outlet for expired air; *c*, main cut-off, controlling gas and air (open for gas only in present position); *d*, cut-off controlling gas and ether (open to gas only in present position); *e*, entrance for air (only air is inhaled when cut-off *c* is thrown forward); *f*, entrance for air to ether cup (closed by sliding cover).

ing the gas entrance to a similar extent; after a few breaths, it is carried a little farther forward to half, two thirds, and finally the full distance, shutting off the gas taken apart, easily kept clean, and packed in a small space.

10 WEST THIRTY-EIGHTH STREET.

FIG. 2.—*a*, compartment for sponge in ether cup; *b*, space for ether vapor; *c*, valve preventing expired air from returning either to gas reservoir or to ether cup; *d*, valve allowing escape of expired air; cut-off *e* carries a pointer with a scale, and is so arranged that as it is thrown forward ether is admitted and gas shut off to a similar extent.

entirely and giving pure ether vapor, the transfer occupying about a minute and a half or two minutes. The inhaler is kept constantly in place until the ether anesthesia is well advanced, and then is replaced by any other cone, a closed inhaler being unnecessary. If it is desirable to give air at any stage of the anesthesia, on account of cyanosis or irregular breathing, it can be done by manipulating cut-off *c*, without removing the inhaler from the face. The opening *f*, with a sliding cover, is used to allow air to enter the ether cup after

A MODIFIED SIEGLE'S PNEUMATIC EAR SPECULUM.

By EMIL AMBERG, M. D.,
DETROIT, MICH.

IN using the Siegle's pneumatic ear speculum I found the light reflected from the glass a disturbing factor. To overcome this difficulty I tried to place the source of light inside the instrument. Following my suggestions, George Tammann & Co., New York, have made a very satisfactory instrument, which is shown in

the accompanying illustration. A small electric lamp is used, so placed that the light rays do not interfere with the examination. They are reflected by a concave mir-

ror into the meatus. Tips of different sizes for the meatus can be attached to the instrument. The tips are to be covered with pieces of rubber tubing.

32 WEST ADAMS AVENUE.

Miscellany.

A Statue to Sir Thomas Browne, M. D.—We are glad to learn from the *Medical Review of Reviews* for April that a statue is to be erected at Norwich to Sir Thomas Browne, M. D., the scholarly author of the *Religio Medici* and many other works on medical and philosophical subjects. He was one of the brightest literary stars of England in the seventeenth century, and is ranked by James Russell Lowell with de Quincy and Jeremiah Taylor as "the richest and most dazzling of theoreticians; our most imaginative mind since Shakespeare." He graduated in arts at Oxford, and in medicine at Leyden, and subsequently at Oxford also, and settled in the practice of physic at Norwich.

Misunderstood.—"Be patient!" growled the leech. "Patient, indeed! Why, I am always patient. I sit like Patience on a monument."

"I thought they lay under one," mildly suggested a brother officer. And again there are strained relations.—*Echoes from a Mining Camp.*

Who Laughs Last Laughs Best.—The *Chicago Medical Recorder* for April has the following: In a recent discussion on the subject of fracture of the patella, before the Chicago Medical Society, Dr. Daniel T. Nelson of this city stated that in 1881 he had the privilege of seeing Sir William MacCormac wire a fractured patella at St. Thomas's Hospital, London. Sir William at that time stated that he had no fear of septic infection of the joint and expected to get bony union. Dr. Nelson called attention to the fact that when he treated the Prince of Wales the operator was less bold. Having called the attention of the great London surgeon to the apparent discrepancy, he received the following letter, which will be of interest to all:

15 HARLEY STREET, W., May 1.

"MY DEAR SIR: I have to thank you for the paper you have been kind enough to send. Since the conversation with me you report I have sutured in many cases

of fractured patella, but not then nor now do I consider it an exclusive method of treatment nor that by it alone can good results be obtained. In the case of H. R. H. to which you refer, I did not consider it a suitable case for suture, and I also hoped and believed that a good result was attainable without. In this opinion my colleagues concurred.

"You will be glad, I am sure, to learn that this opinion has been justified by the result, a short, thick fibrous band, which permits H. R. H. to use the limb practically the same as before. He has not the smallest limp, even, and some of the surgeons present when the prince came the other day to the Royal College to hear my Hunterian oration, failed to detect which limb had been the injured one. So the 'joke' is not so bad a one after all.

Faithfully yours,

"WILLIAM MACCORMAC."

The Creed of the Spiritual Healer.—According to the *Lancet* for April 29th, the *Critic* publishes some amusing verses on the creed of the spiritual healer. Two members of this sect, says the *Lancet*, which seems to be another name for the Christian Scientist, have informed an interviewer that to keep in good health "what you want to do is to think that you can't be ill. Try and (sic) remember that the body is nothing." The poet of the *Critic*, after musing on the foolishness that has beset men who for generations have suffered and even died without using so easy a therapeutic measure, sings thus:

For the body's nought at all;
Rich and poor and great and small,
Thin and fat,
Man is nobody; you'll note
There is nothing in his coat
Or his hat.

Should you lose your legs, anon,
Never think of grafting on
Legs of cork;
Don't believe you're even lame,
Put your boots on all the same,
Rise and walk!

Never work and ne'er be sad;
Hunger's nothing but a fad;
Feed the mind.

When on nothing you are cloyed,
If you feel a kind of void—
Think you've dined.

A Huge Microbe!—The *Quarterly Medical Journal for Yorkshire* (England) and the *Adjoining Counties* for April says: "We take the following advertisement from a daily paper:

"*Notice to the World.*—The Divine, the Hero of Consumption, I now tell one of the wise, that it has offered the Gauntlet, to the greatest in the World, and the Prince of Science not exempt. Dare the Star of Science now accept the gauntlet, or any other great Consumption Treater, who thinks he is master? It has spoken loud enough to be understood, viz., January, 1898, and also in March, 1898, in three leading papers of Yorkshire. Why has it not met with the respond it demands? Is it because they fear it? or is it because they have not the courage to encounter it? What Medicine on Earth can boast of cutting lumps of black clotted blood and a portion of the decayed Lungs and

bringing up the Microbe, 1½ inches long, and driving the huge matter through the bowels, with a smell almost impossible to bear? What Medicine has killed Galloping Consumption three times in one Person? If such Medicine is in the possession of any man, I now dare it to come forth and show to the world who is Master of Consumption. The day and hour can not be too quickly named for business. This should suffice the London Gentleman. The Divine and knowledge is ready at a moment's notice, and will show the World that — is the only place where such a Medicine exists. I want no humbug. I am ready for war, and mean business at once. I think the Learned Gentleman will see now what I mean.

Yours truly,
* * *

And yet there are fools enough, not only in England, but here in America, and in every civilized country, to afford a substantial income to the professor of such balderdash!

The Self-Limitation of the Physician's Aims.—Dr. John E. Harper (*Plexus*, April), in an address on Success in Medicine, delivered at the graduating exercises of the College of Physicians and Surgeons of the University of Illinois, related that Sir Henry Holland, in his eighty-fifth year, wrote a sketch of his life, and said that it would be profitable for each of the new graduates to read it. He began practice, at the age of twenty-one, among the aristocracy in the West End of London, and at the outset made the following two resolutions: 1. That he would never practice more than ten months in any one year, spending the remaining two months in travel and recreation. 2. That he would never allow his practice to exceed fifty thousand pounds per annum. He never broke either rule, although he practised sixty-four years, and several times collected in one year the amount to which he had limited himself. He numbered seven prime ministers of England among his patients, and was physician extraordinary to the Queen. He attributed his long life, good health, and remarkable success in his profession to a strict observance of the two rules made at the beginning of his medical career.

A Testimonial to Dr. G. D. MacGauran.—At the last meeting of the New York Celtic Medical Society the members presented to Dr. MacGauran a handsome service of silver. The presentation speech was made by Dr. Francis J. Quinlan, who referred in high terms to the work done by Dr. MacGauran for the science of medicine, and also spoke of the loss that the city would sustain in the departure of Dr. MacGauran, who goes to Lawrence, Massachusetts, in consequence of his wife's state of health. Speeches were made by Dr. Connelley, Dr. MacGuire, Dr. O'Brien, Dr. MacGowan, Dr. Morrissey, and Dr. Cronin, and responded to by Dr. MacGauran, who referred feelingly to his early association with the society, and how he had watched it grow up under the leadership of men destined in the future to direct not only county, but national societies.

Medical Officers as Administrators.—The *Irish Navy Journal* for May 13th quotes the *London Times* and *Navy Gazette* as saying of General Leonard Wood: "On the principle, we suppose, of *ne sutor supponit crepidum*, it has been urged that medical officers should make indifferent governors or, as in India, 'Residents,' and we can remember some hard words used by a retired and well known Indian civil servant about the administration of a medical officer who occupied one of

the distinguished positions to which we advert; while dissenting from the view alluded to, it is of public importance to draw attention to the career of Major-General Leonard Wood, of the United States Volunteers, military governor of the province of Santiago de Cuba, who in 1883 joined the army of the States as a surgeon. He is a conspicuous example of the special fitness for organizing and administrative work under new conditions which seems to be developed by medical training."

The Royal Army Medical Corps.—According to the *Lancet* for April 29th, it was recently announced in the British Parliament that, owing to the redress of the long-standing grievances of the army medical officers by the creation last year of the Royal Army Medical Corps on a self-containing and self-administering regimental footing, the lack of medical officers, which has prevailed of late years in the British army, is being overcome, and they are already able to obtain two candidates for each vacancy in the corps.

A New Quarterly Journal.—It is announced that on June 1st the first number of the *American Medical Quarterly* will be issued. It is to be published in New York, but edited in Buffalo, by Dr. William Warren Potter. Dr. Potter's experience as a medical editor, his wide knowledge of the profession in the United States and Canada, and the high esteem in which he is held make it certain that the new journal will be creditable and influential.

A Tribute to Dr. Thaddeus A. Reamy, of Cincinnati.—On Dr. Reamy's seventieth birthday, April 28th, a hundred and seventy Cincinnati physicians held a banquet in his honor. We learn from the *Indiana Medical Journal's* account of the entertainment that Dr. P. S. Conner acted as toastmaster and that the speeches were excellent.

The Section in Laryngology and Otolaryngology of the American Medical Association.—This year's programme contains forty-seven items, including an address by the chairman, Dr. Emil Mayer, of New York. The second day's sessions will be held jointly with the Section in Ophthalmology.

What a Blow with an Axe may do.—At the recent meeting of the South Carolina Medical Association Dr. D. M. Crosson, of Leesville, related a case that had occurred in his practice a number of years before. A quarrel arose between two negroes who were chopping wood, and one of them dealt the other a vicious blow with an axe. The wound extended from the outer edge of the right ear, which it severed, forward and slightly downward, fracturing the ramus of the jaw, wounding the external carotid artery, and reaching forward nearly two thirds of the length of the body of the jaw. The man bled profusely, and would have been dead before the doctor arrived, but for the presence of mind of another negro, who stuffed cotton into the wound and made pressure on it. As it was, he was almost dead. Dr. Crosson hurriedly put off the handle of a scalpel beneath the common carotid, where he was able to do by forcing the instrument downward, free the vessel toward the surface, and tied it. After an effort he succeeded in bringing about reaction, adjusted the fragments of the broken bone, and cleaned and sutured the wound and dressed it antiseptically. For three or four weeks the man had to be fed with liquids through a tube passed

in at the opposite side of the mouth. Only moderate suppuration resulted, the broken bone united firmly, and the wound healed, leaving a comparatively small scar. "Since his recovery from the terrible cut," said Dr. Crosson, "he has been a most grateful patient, and has paid me every dollar of his bill, which was made moderate owing to his indigent circumstances. He is now in good health and labors hard every day."

The American Medico-psychological Association.—The fifty-fifth annual meeting will be held in New York, on May 23d, 24th, 25th, and 26th, under the presidency of Dr. Henry M. Hurd, of Baltimore. In addition to the president's address, the following papers will be presented: Address of Welcome, by the Right Reverend Henry C. Potter; address of welcome on behalf of the medical profession of New York city, by Dr. Edward G. Janeway; The Practical Value of Prophylaxis in Mental Disease, by Dr. A. B. Richardson, of Massillon, Ohio; Progress in the Clinical Study of Psychiatry, by Dr. Edward Cowles, of Waverley, Massachusetts; The Imagination in Relation to Mental Disease, by Dr. R. H. Chase, of Philadelphia; Remarks on Contagion and Infection in Insanity, and Measures of Prevention, by Dr. Richard Dewey, of Wauwatosa, Wisconsin; The Role of Wound Infection as a Factor in the Causation of Insanity, by Dr. A. T. Hobbs, of London, Ontario; The Puerperal Insanities, by Dr. H. A. Tomlinson, of St. Peter, Minnesota; The Relations of Renal Disease to Mental Derangement, by Dr. W. L. Worcester, of Danvers, Massachusetts; Paretic Dementia—its Ætiology, by Dr. Sanger Brown, of Chicago; The Differential Diagnosis of Paretic and Pseudo-paretic States, by Dr. Arthur W. Hurd, of Buffalo; Lesions of the Intracranial Vessels in Brain Syphilis and Paresis, by Dr. Henry J. Berkley, of Baltimore; Vocation and Paretic Dementia, by Dr. Joseph G. Rogers, of Logansport, Indiana; Our Work and its Limitations, by Dr. E. C. Runge, of St. Louis; The Legal *versus* the Scientific Test of Insanity in Criminal Cases, by Dr. Carlos F. MacDonald; The Psychology of Criminals and a Plea for the Elevation of the Medical Service of Prisons, by Dr. J. B. Chapin, of Philadelphia; Some Inconsistencies, Legal and Medical, about Insanity, by Dr. J. T. Searcy, of Tuscaloosa, Alabama; Judicial Errors in Lunacy, by Dr. George Villeneuve and Dr. E. P. Chagnon, of Longue Pointe, Quebec; Annual Address, by Dr. Frederick Peterson; Thyroid Extract—its Place in the Therapeutics of Insanity, by Dr. William Mabon and Dr. W. L. Babcock, of Ogdensburg, N. Y.; Reflex Irritation, with Special Reference to Eye Strain—A Factor in Nervous and Mental Disease, by Dr. Charles A. Drew, of State Farm, Massachusetts; Epileptical Mania, by Dr. T. J. W. Burgess, of Montreal; Disorders of Sleep among the Insane, by Dr. Theodore H. Kellogg; The Boarding-out Treatment of the Insane in America, by Dr. G. Alder Blumer, of Utica, N. Y.; The Nature and Principles of Psychology, by Boris Sidis, Ph. D.; The Physiological and Morphological Basis of the Retraction Theory, by Dr. Ira Van Gieson; The Retraction Theory from a Psychical Standpoint, by Dr. William A. White, of Binghamton, N. Y.; The Internal Structure of the Ganglion Cell, by Dr. Stewart Paton, of Baltimore; The Desirability of Close Connection between Psychological Laboratories and Hospitals for the Acutely Insane, by Dr. Samuel B. Lyon, of White Plains, N. Y.; The Pathology of Epilepsy, with an Introduction to a New Treatment, by Dr. Charles G.

Hill, of Baltimore; The Public Care of the Epileptic in Massachusetts, by Dr. Owen Copp, of Palmer, Massachusetts; The Treatment of Epileptics in Colony, by Dr. J. Frank Edgerly, of Oakbourn, Pennsylvania; The Palates of Idiots, by Dr. Walter Channing, of Brookline, Massachusetts; Hospital Dietary, by Dr. F. C. Hoyt, of Mount Pleasant, Iowa; Inhibition of Speech and Writing, by Dr. Richard Dewey, of Wauwatosa, Wisconsin; A Review of the Literature Published for the Instruction of Nurses in Institutions for the Insane, by Dr. William D. Grainger, of Bronxville, N. Y.; Metaphysics, by Dr. H. C. Eymann, of Cleveland; The Importance of Better Cooperation and Organization among Private Hospitals for the Insane, by Dr. J. J. Kindred, of Astoria, N. Y.; and Christopathy—A Glance at the Neuropathic Side of Christian Science, by Dr. C. H. Hughes, of St. Louis.

The New York Academy of Medicine.—At the stated meeting, on Thursday evening, the 18th inst., the following papers were to be presented for discussion: Recent Methods of Local Anæsthesia for Minor and for Major Surgical Operations, by Dr. Alexander B. Johnson; Further Experimental Researches on the Effects of Different Anæsthetics upon the Kidneys, by Dr. Robert Coleman Kemp; Technics of Administration of Anæsthetics, by Dr. Thomas L. Bennett.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 24th inst., the following cases are to be presented: Healed tuberculous laryngitis with pulmonary tuberculosis remaining active, by Dr. T. P. Berens; salivary calculus, by Dr. W. Freudenthal; tuberculosis of the nose, throat, and larynx, without manifest pulmonary involvement, by Dr. C. G. Coakley; marked displacement of the cartilaginous septum in a child, by Dr. W. C. Phillips; a case illustrating the Watson operation for deflected septum, by Dr. R. C. Myles; and endothelial sarcoma of the nose, by Dr. M. D. Lederman. Dr. D. H. Goodwillie exhibited casts of the nose, and Dr. H. H. Curtis exhibited two radiographs of the antrum, showing intruding teeth.

The Late Dr. Charles Mason, of Peekskill.—Dr. Charles Mason, who for nearly a quarter of a century lived and practised his profession for the benefit of the residents of Peekskill and vicinity, is now no more. Stricken in robust health, while performing his duty, he passed quietly over to the silent majority, April 19, 1899.

We, the members of the medical staff of the Peekskill Hospital, in commemoration of the fact that he was one of the original board and that his work as such was of the type of recognized ability, desire to lay this, a tribute of worth, upon his tomb, and to convey to his family an expression of our sincere sympathy.

THE GENERAL DIAGNOSIS OF
SYPHILIS OF THE BRAIN AND
SPINAL CORD.*

By B. SACHS, M. D.,

PROFESSOR OF MENTAL AND NERVOUS DISEASES IN THE NEW YORK POLYTECHNIC
CONSULTING NEUROLOGIST TO MOUNT SINAI HOSPITAL, ETC.

I HAVE construed my especial part in this symposium—a merry name for a serious talk—as a summons to place before you, in as concise a form as possible, the chief points in diagnosis by which the physician shall be able to recognize syphilis of the nervous system. It shall be my endeavor to present such views as are firmly established, and to touch upon mooted points only if their discussion be of special interest. Not many years ago specific affections of the nervous system were diagnosed largely by exclusion. If the symptoms did not point to anything else of a definite character, they were often attributed to a preceding syphilitic infection, and the diagnosis was as often incorrect as it is apt to be when this method is adopted.

The general practitioner may be supposed to be interested first of all in the question of the frequency of specific affections of the central nervous system. Statistics are not easily gathered on this point, for it is difficult to keep track of those who have acquired syphilis; but Hjelmlan† states, on what appears to be good authority, that fifteen to twenty-five of each one thousand persons affected with syphilis develop some specific disease of the central nervous system, excluding those who develop either tabes or general paresis, and both these diseases have a very important, if not an intimate, relation to constitutional lues. The majority of the able writers on the subject are under the impression that syphilitic nervous disease appears to be on the increase; if so, this fact can be explained on the assumption that under the present social conditions, in view of the great struggle for existence on the part of the majority of the people, the strain to which the nervous system is subjected makes it an easier victim to any constitutional poison, whether that be syphilis, alcohol, tobacco, or what not. We neurologists are also pleased to think that the increase may be apparent only and does not mean a clearer understanding of the specific forms of brain and spinal-cord disease.

Syphilitic nervous affections are naturally considered to be a manifestation of constitutional disease, in accordance with the prevailing doctrine, and are held to follow naturally in the wake of an ulcus durum. We have some hesitation in claiming that these manifestations ever follow upon the soft chancre, and

not do to enter into a discussion of the relation between these two early lesions and constitutional syphilis. I have been taken to task for a statement made some years ago* that syphilis of the central nervous system occurs in conjunction with the lesser form of the initial infection, but it is a satisfaction to record that others hold the same view. Without fear of contradiction it may be said that these affections of the nervous system do occur not infrequently in patients who give a clear history of soft chancre. I am willing to leave it to the syphilographer to decide whether under such circumstances he would or would not diagnose constitutional syphilis. Hjelmlan and others are of the opinion that the greatest number of cases of cerebral syphilis result from mild and moderately severe forms of the disease, and with this view my own experience would lead me to agree. Whether or not the later invasion of the central nervous system is dependent upon the character of the initial treatment is a matter still under dispute. It can not be denied that many of the severest forms of nervous syphilis which we are called upon to treat have been handled unsatisfactorily in the initial stages; in many other cases the initial treatment has been all that could be desired. It will be wiser, therefore, to be liberal in our interpretation of the sufficient or insufficient amount of treatment, and to give every patient presenting the symptoms of syphilitic disease of the nervous system the benefit of another and most thorough course of specific remedies.

It was a satisfaction to hear several previous speakers question the propriety of maintaining the old-fashioned classification into secondary and tertiary forms, for syphilis of the nervous system is not always a late manifestation of the constitutional disease. In fully eleven per cent. of cases of syphilis of the brain the cerebral symptoms have occurred within the first half year after the initial infection, and in 24.6 per cent. of all the cases (the largest percentage) between six and ten years after the primary sores.† I have known a specific form of facial palsy to occur almost simultaneously with the initial lesion, and have seen undoubted spinal symptoms appear within six weeks, together with the characteristic rash.

The brain and spinal cord are affected very much more frequently than are the peripheral nerves, but whether the disease happens to involve one or the other part of the nervous system is completely governed by a very definite series of general conditions, which can be best understood and interpreted if we attempt to examine into the morbid lesions that are concerned.

It may be considered that the most important benefits of the general discussion were those which showed that the

* Read before the New York Academy of Medicine as part of a general discussion on syphilis, March 16, 1899.

† Review in *Neurolog. Centralblatt*, 1894, p. 342.

lesions in the nervous system will appear to be not unlike those affecting other organs. In the brain and spinal cord, syphilis may become manifest by the formation of special growths (gummata), by the development of a gummatus infiltration starting from the meninges, which may be associated with single, well-defined tumors, and which may or may not invade the substance of the brain or of the spinal cord; and lastly, it may do mischief through disease of the blood-vessels. Gummata occur most frequently upon the convexity, at the base, and in the internal ganglia of the brain; they are less common in the spinal cord. These gummata may at times attain the size of a walnut, or even of a chicken's egg, but miliary gummata are not unknown. Granulation tissue forms the stock of this tumor, consisting largely of closely packed round cells. The intercellular substance is generally of the order of connective tissue filled out by these newly formed cells. Star-shaped, spindle-shaped, and even giant cells are found interspersed among the round cells. The whole mass is more or less vascular, the blood-vessels being frequently contracted and often obliterated. It was Virchow who first pointed to the fact that the granulation tissue in syphilitic new growths is unproductive; that it has but a short span of life, and that while there may be some proliferation, there is at a very early day a retrogressive metamorphosis. This leads to a simple atrophic process which often ends in a caseous formation. It is this self-limitation of the syphilitic neoplasm, whether or not it is influenced by therapeutic measures, which is of the utmost importance; and if we add that this syphilitic process emanates, as a rule, from the capillary vessels, we have said all that we need to say with a view to the relation between this special morbid lesion and some of the clinical features dependent upon them. A solitary gumma is rare; in fully ninety-five per cent. of the cases there are many such multiple tumors, which may be associated with a diffuse infiltration of the meninges, from which it takes its start. The neuroglia, the ganglion cells, and the nerve fibres do not provide the soil upon which the new growth is established, but the connective tissue of the meninges, in some instances the periosteum of the cranial bones or of the vertebrae, are the starting points of the entire process.

It has just been intimated that the capillary vessels are important factors in the development of the syphilitic neoplasm, but the larger blood-vessels of the brain, as well as those of the spinal cord, are the seat of changes which, since the brilliant investigations of Heubner, are known to be due to the syphilitic virus. To be brief, syphilitic disease of the blood-vessels is generally manifested by changes in the intima. Specific endarteritis has become almost a byword in neuropathology, but all the coats of the blood vessels may participate in this proliferating process. Oppenheim, Siemerling, and others have shown conclusively that a periarteritis

may be the primary change, the blood-vessel itself becoming diseased in secondary fashion. But whatever the nature of the arterial disease may be, it leads ultimately to an occlusion of the blood-vessel, with subsequent softening of the area supplied by the same. It is characteristic of this form of arteritis that the occlusion need not be permanent, and that several attempts may be made to block the blood channel before actual success in this direction is obtained—a fact which it is well to bear in mind in connection with the many transitory symptoms so characteristic of brain- and spinal-cord syphilis. However carefully these various changes have been studied, the fact remains that the morbid lesions *per se* are not so different from others that they can be recognized in every instance as truly syphilitic in character. Unfortunately, the bacillus of syphilis, in spite of the careful researches of Lustgarten, Disse, Taguchi, and others, has not yet been satisfactorily revealed, and the resemblance to tubercular, and even sarcomatous, affections is striking enough to bother at times the experienced pathologist. The general character of the morbid manifestations, the multiplicity of the lesions, the evidences of a tendency to retrogressive changes, to the formation of scar tissue, and the general benign character of the process will help to a proper recognition of the nature of the lesion. There is much of interest to be said in connection with this special part of the subject; * but I leave it at this point, for I am concerned with the morbid process in so far only, as an understanding of the same helps us to a proper interpretation of the clinical symptoms.

If we were to attempt to construct the symptomatology of brain- and spinal-cord syphilis from a knowledge of its morbid anatomy, we should be justified in maintaining that syphilis of the central nervous system is characterized above all by the multiplicity of the symptoms, and by a tendency to remissions and relapses, which is quite in keeping with the tendency on the part of the tissue to proliferate and undergo retrogressive metamorphosis. Moreover, while the syphilitic process invades or encroaches upon nerve tissue, it is not rapidly destructive, whence it follows that syphilitic disease of the central nervous system may lead to a variety of symptoms, none of which is necessarily complete. No other disease gives rise so often as syphilis does to paresis rather than to paralysis; to slight rigidity rather than to contractures; often to partial, rarely to complete anaesthesia; to transitory and incomplete aphasia rather than to permanent and absolute loss of speech. These general symptoms will serve to indicate the character of the morbid process, all other manifestations being dependent upon the special localization of the disease in some one or in several parts of the central nervous system. As you view the charts before you, you

* Cf. previous writings on this subject: N. Y. Med. Jour., Sept. 19, 1894; Brain, xvi, 1893; Nervous Diseases of Children, 1895, chap. xviii.

will infer that if the disease affects the convexity of the brain, you may have headaches, loss of intelligence, delirium, even coma. You may also find the patient afflicted with paralysis or with epileptoid attacks, particularly if the motor area is the part invaded. If the speech centres be affected, aphasia is the result; and in syphilis motor aphasia is much more common than the sensory forms. Apoplectic seizures with accompanying hemiplegia result from disease of the internal blood-vessels of the brain. If the disease involves the structures at the base—and this is the seat of predilection—cranial nerve symptoms, above all ocular palsies, are the most common clinical manifestations. If the luetic process invades the spinal cord, you will find the symptoms which are to be specially attributed to disease of the cervical, dorsal, lumbar, or sacral segments of the cord. Note also that with the invasion of the anterior, the lateral, or the posterior divisions, there will be either atrophic and paralytic, spastic and paralytic, or sensory symptoms. In some instances one or two or all of these divisions may be affected, and you may construct for yourselves the vast variety of symptoms. No set of symptoms is pathognomonic of syphilis of the brain or spinal cord, and I would not weary you with all the details of localization, which can, after all, be gathered easily enough from a few hours' study of the general structure of the central nervous system; but, as in so many other instances, it may safely be said that the question of *localization* of the lesion has been very much overdone in comparison with that far more important point—namely, the *character* of the lesion. Whatever the special symptoms in a given case may be, one is not likely to go astray in suspecting syphilis if there is evidence of multiplicity of the lesions and of the incomplete character of the symptoms, as well as of a tendency to remissions, to relapses, and to recovery.

A word about the multiplicity of the lesions, the point upon which, by the way, Dr. Fox so ably insisted in his demonstration of cutaneous syphilis. There are but few diseases affecting the nervous system which give rise to multiple lesions. If we mention multiple sclerosis, tuberculosis, and sarcomatosis, we have well nigh exhausted the list. Tubercular and sarcomatous diseases are so much more malignant, run so much more rapid a course, and are so apt to manifest themselves in other organs of the body that the differential diagnosis can be established easily enough. It is not so easy to distinguish between syphilis of the nervous system and multiple sclerosis, for both have a tendency to remissions and relapses, though in the case of multiple sclerosis a complete cessation of the symptoms is very much rarer than in syphilis; the peculiarities of speech, the nystagmus, the intention tremor, will in nine cases out of ten help us to recognize multiple sclerosis.*

Multiplicity of symptoms in syphilis need not imply that all the lesions are coexistent. We know that the syphilitic morbid process may at any one time give rise to a transitory hemiplegia, or to distressing headaches, three months thereafter to ocular nerve palsies, and a year later to spastic spinal symptoms. I wish to insist on this special point, because it is often overlooked.

With these characteristic signs of cerebro-spinal syphilis in mind, let us proceed to ask whether there are any special symptoms which have a sufficient pathognomonic value. In a general way, it may be said that syphilis produces symptoms that are not likely to occur in the middle term of life from any other cause. Apoplectic seizures in the absence of cardiac renal disease are always suspicious. Persistent headaches and epileptiform seizures have, under the same conditions, a similar value. Spastic paralytic symptoms of the lower extremities that do not follow upon injury to the spine or other tangible cause, such as bone disease, are also suspicious, particularly if they occur in adolescence or in middle life. But of far greater value than all these other symptoms is the peculiar behavior of the pupils. If syphilis is clearly written upon the skin, as has been well said, it is still more clearly visible in the pupil of the eye, and this is true not merely of the behavior of the pupils in the presence of other manifestations of syphilitic disease of the nervous system, but also at times when all other signs of such disease are wanting. A close study of many years with reference to this special point has led me to attach more importance to the behavior and condition of the pupils in syphilitic disease than to the peculiar bone manifestations, or that rather notorious epitrochlear gland after which we go so often on a still hunt. I would even venture to state that I have more frequently had reason to suspect and to prove the presence of constitutional syphilis from a study of the pupils than from any other symptom that the patient may have presented. The peculiarities to which I refer are these:

First, inequality of the pupils—one contracted, the other dilated.

Second, unequal responses—the one reacting to light, the other failing to respond.

Third, the complete immobility of the pupils both to light and during accommodation. The Argyll Robertson pupil, though so characteristic of tabes and of paralytic dementia, is not necessarily typical of syphilitic disease. The complete immobility of the pupils as evidence of syphilitic disease has the sanction of no less a name than that of Jonathan Hutchinson, but the knowledge of its great value has not entered sufficiently into the general literature of the day.

Fourth, and this I would add with some diffidence, marked departure from the normal form in cases in which there has been no previous tabes. These irregular contractions become more apparent when the pupils are made to contract by the usual stimuli. I will not

* See an article by the present writer in *Journal of Nervous and Mental Disease*, 1898, p. 320.

deny that this is met with at times in persons in whom other syphilitic manifestations are entirely wanting, but it is so much more common in syphilitics that it has been of sufficient value to me to lead me to suspect syphilis in very many persons in whom, on further investigation, I have found ample corroboration of the diagnosis. If you would suspect or prove the presence of syphilis when it is not too clearly written upon the skin, do not fail to study the pupils.

One of the ablest writers on syphilis of the nervous system* states that the diagnosis rests chiefly upon proof of a preceding luetic infection. It is not my purpose to deny the weight of such evidence, nor to under-rate the famous triad of symptoms which we owe to Hutchinson, or those which have been more recently enumerated by Silex. The latter attaches much importance to a form of chorioiditis areolaris, to the linear scars about the mouth, and to the well-known changes in the upper incisors. For many years since the publication of my first article on the subject, I have endeavored to show that the diagnosis should be made independently of such evidence, and I now believe that it can be done with as much certainty in syphilis of the nervous system as with regard to tuberculosis or sarcoma in any part of the body. Aside from the symptoms before enumerated, there are several symptom groups which follow so frequently upon invasion of the central nervous system that their appearance suggests the probability of constitutional syphilis. It is generally known that chronic, diffuse headaches in an otherwise healthy individual, continuous for days, but often intermittent, possibly worse at night, but not necessarily so, yet dependent largely upon the position of the head, are of syphilitic origin. It is not so well known that vertigo, which may be dependent upon a lithæmic state, and is often attributed to disease of the ear, to ocular insufficiencies, and the like, is also likely to be one of the early symptoms of cerebral syphilis. If such vertigo occurs in middle life, this fact should not be lost sight of.

I can well remember the case of a Canadian physician who had traveled the world over to find out the special cause of a vertigo which made life almost intolerable. It was unaccompanied by headaches or by any other of the well-known general symptoms of cerebral or spinal syphilis, but he had unequal pupils; the one was mobile to light, the other responded faintly, and as every other treatment had utterly failed, I concluded that a specific endarteritis, with a resulting disturbance of cerebral circulation, might be the cause of this vertigo, and was gratified to find that it disappeared within a few weeks upon a vigorous antisymphilitic treatment.

Single epileptoid seizures, transitory hemiplegias, and transitory motor aphasias, if they occur in the absence of renal disease, may well be suspected to

be due to this cause. With regard to apoplectic attacks occurring in middle life in persons who have neither renal nor cardiac disease, the apoplexy may safely be attributed to syphilis, particularly if the onset of the symptoms is entirely in keeping with the supposition of a thrombosis of one of the larger vessels, for this thrombosis is the usual accompaniment of a specific endarteritis. With regard to these brain symptoms, it is hardly necessary to state that they are sufficiently explained by the assumption of a chronic, diffuse leptomeningitis, of gummata, or of specific disease of the blood-vessels. The base of the brain is most commonly affected, and here again the lesion involves by preference the interpeduncular space, whence it follows that the optic nerve and ocular motor symptoms are altogether the most common. A lesion in this vicinity will naturally cause marked disturbance of vision, due, as a rule, to optic neuritis; and ocular motor palsies, due to involvement of the third and fourth nerves. The ocular palsies may be transitory or permanent; they may have the characteristics of the nuclear lesion, or may bear all the signs of a complete palsy. Anatomic investigations on this point have shown that syphilis may lead to degeneration of the ocular motor or other cranial nerve nuclei, but what appears to be a nuclear palsy has been shown to be due to a syphilitic infiltration of the extra cranial root fibres of the third nerve, this infiltration choking some of the fibres without invalidating all. It seems to me, therefore, to be important to know that presumably nuclear palsies may be, and often are, of specific origin. This partial affection of the cranial nerve roots has led to many a misunderstanding. I have seen partial affections of the trigemini which have disappeared promptly upon the exhibition of the iodides in persons with undoubted specific histories, and, stranger still, were cases of hypoglossal disease of specific origin. I have in mind a particular patient in whom this lesion, as evidenced by an atrophy of both halves of the tongue, was recovered from, although the spastic paraplegia in the same individual, due to the same underlying disease, persisted up to the time of death.

Syphilitic double optic neuritis deserves attention, for it is a symptom to which neurologists and ophthalmologists give great weight in diagnosing brain lesions. Examination of syphilitic brains in which the optic tracts and the chiasma are found swathed in a characteristic exudate, suggests the thought that in many cases it will be well to bear this possibility of a specific disease in mind before giving an absolutely fatal prognosis. Specific disease involving the optic chiasm is all the more interesting because it gives rise to disturbances of the visual field, which could hardly be explained upon any other supposition than that of a partial infiltration of the nerve fibres composing the chiasm and the optic tracts. Ocular nerve palsies of varying kinds are often among the earliest symptoms of tabes dorsalis, and many years ago I raised the ques-

* Oppenheim *loc. cit.*

tion whether some of these forms of tabes, beginning with ocular palsies, are not truly specific types of cerebro-spinal syphilis. If any of these basilar symptoms are associated with others which point to the involvement of distant parts of the central nervous axis, symptoms which could never be due to a single lesion, the suspicion of an underlying specific disease is raised almost to a certainty. It is indeed astonishing to find how often brain symptoms are associated with those pointing to disease of the lower or lowest portions of the spinal cord. In 1891* I described this special type of disease under the term of multiple cerebro-spinal syphilis. One of the cases upon which this type was based, was that of a woman who at one time exhibited cranial nerve symptoms and a paraplegia of the lower extremities from which she recovered, and later on developed all the symptoms of a tumor of the pons with other manifestations, which could only have been due to a simultaneous involvement of the dorsal and lumbar portion of the cord. The post-mortem examination revealed a broken-down gumma in the pons, and marked meningeal exudate around the oculo-motor nerves around the medulla oblongata, the cervical and lumbar portion of the spinal cord. No better evidence was needed that syphilis may affect simultaneously the brain and the spinal cord.

If we pass to a consideration of the special symptom groups due to syphilitic disease of the spinal cord, we shall find that recognition of these is a tolerably easy matter. Bear in mind, if you will, that the disease starts in the majority of instances from the meninges; that it affects the dorsal and lumbar portion of the cord more frequently than the cervical, and that the disease invades the lateral column much more frequently than the anterior or posterior regions of the cord; whence it follows that spastic and paralytic symptoms, which may be symmetrical, but often invade one side long before the other is diseased, are suggestive of spinal syphilis. If we also bear in mind that invasion is a gradual one, that it is not rapidly destructive, we can understand why these spastic and paralytic symptoms chiefly in the lower extremities may exist for a long period of time without any of those other signs which are so common in affections of the entire cross-section of the cord; and it is also clear why the paralysis may last for years before it becomes complete, and why the involvement of the vesical and rectal centres may lead to a slight involvement of the locomotive sphincters without causing a complete loss of control. Sensory symptoms, if superadded, may be of a slight kind. Erb has insisted that this spastic paraparesis with slight anæsthesia, and moderate rigidity with minimal involvement of the sphincters, is particularly characteristic of what he calls the syphilitic spinal syndrome. Nonne† has shown that this form may be due to a combined

systemic degeneration. I would insist, as I have in previous writings, that this is a form of syphilitic spinal-cord disease and not the only form. Syphilitic disease of the spinal cord causes sensory and atrophic paralytic symptoms often enough to make it uncertain whether it is wise to restrict the term syphilitic spinal paralysis to the spastic forms alone. It is natural to inquire why the lower levels and the marginal regions of the cord should be invaded so much more frequently than the cervical-dorsal segments and the central gray matter. It has been shown that the spinal arteries become very narrow in the lower dorso-lumbar regions; that the postero-lateral regions have a relatively scanty blood supply at all levels, and that while the vascular distribution in the spinal cord, according to Williamson, is unfavorable to the occurrence of hæmorrhage and embolism, it is distinctly favorable to thrombosis. The areas having poorest blood supply will be most likely to undergo softening and will be least able to resist the invasion of a meningeal infiltration. It will be seen at a glance that if a morbid process does invade the posterior portion of the cord, and if before so doing it compresses the posterior root fibres, the symptoms will closely resemble those of posterior spinal sclerosis. I would not urge this point were it not for the fact that the diagnosis of tabes dorsalis, with its unfavorable prognosis, is made altogether too readily whenever any of the symptoms due to lesion of the posterior half of the cord are present. I am firmly convinced that these cases of syphilitic pseudo-tabes can be distinguished from genuine tabes dorsalis, and in the former the prognosis is so much more favorable that the distinction has a distinctly practical value. It has been my experience that in these cases of pseudo-tabes syphilitica the disease often affects one leg long before it does the other; one knee-jerk is present, or only slightly diminished, while the other is already absent; the ataxic symptoms are often very slow to develop, indeed they are in many genuine cases of tabes dorsalis, and, above all, there are in these cases those general symptoms of cerebro-spinal syphilis which I need not now reiterate; though I repeat that it is just in these cases that the absolute immobility of the pupil in contradistinction to the Argyll Robertson pupil gives good reason to believe that what is supposed to be tabes dorsalis, is a syphilitic pseudo-tabes. In a number of such cases I have had the satisfaction not only of seeing a recovery from the accompanying ocular palsies, or a diminution in the reaction of the pupils—a thing which I have never observed in genuine forms of tabes—but I have also witnessed the return of the knee-jerk, even when it had been absent for a long time. I have also seen how many have been absent for a long time in the pseudo-tabes of syphilitic origin, and how they return after clinical fancy, but has been pointed out by my own observations made, among others, by Erb, Sachs, and myself.

Lastly, I might be expected to dwell upon the rela-

* This Journal.

† Nonne, *Arch. f. Psychiat.*, xxix, 3.

tion of syphilitic infection to posterior spinal sclerosis or tabes dorsalis. So far as statistical evidence is of any account, there is overwhelming proof that the two are related. Some years ago Strümpell made the point that posterior sclerosis was a post-syphilitic and not a true syphilitic disease; that the disease was due not directly to the syphilitic poison, but to the toxins which had been formed by this poison and remained latent in the body for a long time. The point has been seized upon with avidity by many writers, but I can not see that it places the disease in any other position than are many of the late manifestations of lues. The chief difficulty that we experience is not in attributing tabes to a preceding infection, but in explaining how this posterior spinal sclerosis may be caused by preceding syphilitic disease. This difficulty is increased by the fact that more recent theories with regard to tabes dorsalis have shown it to be of extraspinal rather than intraspinal region—in other words, that the disease is due to the fact that the posterior root fibres become primarily diseased, either by direct compression before entering the spinal cord, but more probably in consequence of the disease of their nutritive centres in the spinal ganglia, and that the posterior columns appear to be the main seat of the disease, simply because they are made up of the posterior root fibres entering into the cord. If it could be shown that the blood-vessels supplying these ganglia had been the subject of specific endarteritis, much would be gained, but such proof is not yet forthcoming. I am inclined to suspect, in spite of all opposing theories, that specific endarteritis of the spinal blood-vessels may have something to do with the early development of the disease, because in at least one cord which I have examined post mortem, I found distinct endarteritis of the blood-vessels in the midst of sclerotic tissue. Evidence has been adduced, by Adler,* for instance, that there may be disease of the blood-vessels in syphilis of the heart without any symptoms pointing to a cardiac affection; and so I believe that the relation between syphilis and tabes will not be satisfactorily established until a careful investigation of the condition of the blood-vessels of the spinal cord shall have been made in the earliest stages of posterior spinal sclerosis. From whichever point of view we may attack the problem of syphilis of the nervous system, the impression is forced upon us that the disease of the blood-vessels is a primary factor. I need not enter into the symptomatology of tabes dorsalis, but would express the caution that in persons who have been afflicted with constitutional syphilitic disease, the onset of a slight ataxia and a merely diminished response on the part of the patella tendon are suspicious of impending tabes; and if any good is to be accomplished by treatment, such treatment should be instituted before more serious symptoms are developed.

Were I to attempt a further description of syphilis of the brain and spinal cord, it would be necessary to give in detail almost every known symptom-group, and I should have to dwell on some points that are still in controversy. I have said nothing about the cervical types of spinal-cord syphilis because they are, on the whole, rather rare, and I have not referred to a special class of cases which have interested me, because they bear a remarkable resemblance to that rare affection of the spinal cord known as syringomyelia. Suffice it to say that whether the disease affect the cervical, the dorsal, or the lumbar portions of the cord, however much the symptoms due to the exact locality of the part affected may vary, the general symptoms will be the same; and among these the widespread yet moderate development of the morbid signs, showing that the disease is great in extent but slight in intensity, and the unusual variability of the symptoms, with a tendency to remissions and relapses, stamp the morbid process as one that is in all probability due to constitutional syphilis.

INTENTION: A STUDY OF THE BOVINE BRAIN.

BY WALLACE WOOD, M. D.

IF by chance the student or professional man should ever receive into his hands the brain of a bullock direct from the axe of the headsman, he will have occasion to note how full, round, and firm appears the occiput or posterior half, and how flaccid, empty, and pointed in shape appears the sinciput or anterior half.

One naturally asks the reason of this, and the answer would be that the posterior half of the cerebrum is the receiver and holder and the anterior half the transmitter and driver. The posterior, round and hard, is plumped full of impressions; years and years of memories are there stored up in innumerable folds, sights, and panorama slides; innumerable pictures of summers and winters past fill one section, while the corresponding noises, melodies, and voices fill another convoluted mass. Samples, minute yet true, of all the grass and hay ever eaten fill the taste compartment, while in the lowest coil are stored the odors of all the meadows and pastures and the smells of the woods and the marshes. The smell gyrus, indeed, in cattle or dogs, or in any mammal lower than a primate, may well seem to us poor microsmatics a marvel of development. This posterior half has also a full store of kicks and cuts, of pushings and pullings, of combings and carressings, of milkings and yokings, and a thousand forms of contact; and the all-powerful impressions of sexuality and parentality have also there a chamber or place. So it is no wonder the posterior half is round and hard and full.

On the other hand, the sinciput is not a storehouse of these rather worldly and substantial impressions. While the posterior half holds, keeps, combines, arranges,

*Observation on Cardiac Syphilis, *A. J. Med. Jour.*, Oct. 22, 1898.

and rearranges these samples of worldly goods, the anterior end, the point of the pyramid or cone, calls up and transmits the impression or combination required.

The functions of the posterior half are hearing, seeing, smelling, tasting, feeling, and passion; the functions of the anterior half are attention, intention, phonation, and action.

What is attention? Let us see. A bovine animal in the pasture hears a clatter and sees a glare: the crea-

FIG. 1.—Left brain of an ox, exterior surface. The occiput or posterior half is large, full, hard, and well rounded; this is the receiver and store. The snout or anterior half is smaller, softer, and triangular, like the apex of a pyramid. High on the plate to the right is seen the serpentine eye gyrus, or store of sights, and below it, triangular in shape, the ear gyrus, or store of sounds. In the direction anterior-inferior is seen the great triangle or junction, the seat of the attention. Between this and the other parts lies the chasm or vortex of action.

ture stops and stands fixed, "all eyes and ears." What is happening? We may say that the concentrated or anterior end of the brain, the apex of the pyramid, is endeavoring, through the longitudinal or cogitational system of nerves, to call up all similar sights and sounds from the stores of the past in the posterior half and to unite them with the actual present impression. When this is accomplished and recognition is reached, the creature acts. He knows, for instance, that this clatter and glimmer means salt, and he rapidly moves toward the approaching sight and sound. Attention becomes intention, then action, accompanied very probably by phonation.

Where shall we locate these functions? The cerebral eye and ear—that is, the store of sights and sounds—have been found to be respectively the second and third gyri, posterior, counting from the upper margin. The eye gyrus in cattle has much the shape of a stamen, a serpent, or a stemma; it is double or cleft, however—that is, marked by a central groove or fissure. The ear gyrus below it curves sharply, forming a haunch, the temporal eminence, and this eminence, triangular always, with a central incision, bears a certain resemblance to the external bovine ear.

If, now, we place our pen or finger upon the two gyri and move forward across what appears to be a central chasm, and which must be the chasm of action or place of the descending current, we shall find our-

selves at a point of the anterior where the two gyri meet. This anterior junction then is to be regarded as the *locale* or point of attention. Association fibres from this centre must radiate to the eye centres, to the ear centres, to the smell and taste centres. This exterior point, then, is the central office, the seat where sits the man that *knows*. The bullock knows that this sounds like coming salt, looks like it, he knows it is salt.

Having *attended* to this, he now *intends* to obtain his share. Where shall we locate intention, where find or seek for that famous *boule*, *role*, that might of almighties for good or evil, the will?

Where is the *boule*? Where is the intention?

In making dry preparations of the brains of fifty cattle—male, female, juvenile and neuter—I found that the bull brain is distinguished by a highly developed prow or precan lobe, and this upon the mesial or inside surface. In other words, the bull has a tremendous cerebral development exactly *between the eyes*; while the brains of his sisters, the cows, have usually no such development of folds and fissures at this point, and his unfortunate brothers, the oxen or bullocks, if weighed in the balance as to their mesial precan lobules, will be found very much wanting.

That Taurus, the bull, when in full maturity and at the height of his power and splendor, is one of the noblest of the Creator's works all will concede; but what is that peculiar, that transcendent quality which, from the days of the pyramids of Egypt and the worship of Apis to the last days of Spanish rule in the West, has made this creature so respectable, so redoubtable, so admired and feared?

What is this bully good quality? Is it not the will, the intention, the *boule*? Whatever it is, I am strongly

FIG. 2.—Right brain of a mature bull, exterior surface. The prow or anterior extremity is different from that of the cow. It is highly convoluted and highly developed.

of the opinion that the centre or point of attention is between the eyes, and that it is definitely placed upon the prow, the precan region, the precan lobe, of the mesial surface.

Once more, What is the quality of the bully good? For a moment look back to the beginning of this natural or wild state: the bully good quality will be seen

to be this: the intention, the determination to protect or defend.

It is the *boule*, the *volé*, the tremendous intention or determination.

What are your intentions? A question of vital importance if you stand in a lone pasture with this famous and formidable animal approaching you. *Where* are your intentions? is the question less vital, but not without interest, that you ask as you hold the left bovine semicerebrum in one hand and the scalpel in the other. And I should be inclined to answer, "In the prow." Observation seems to show that the brain of the male bovine tends to a procran development, and that of the female to a metopic development. If this is true, would it not suggest that the prow may be the seat of determination, intention, the *βωλῆ*, strong will, while the metopon is the gathering point of submission, willingness, *lunoia*?

RETENTION OF URINE.

By RAMON GUITÉRAS, M. D.

(Concluded from page 659.)

Treatment.—The treatment in retention of urine varies and depends upon the cause, form, and degree of the trouble, and may be divided into temporary palliative and radical methods. It is my intention here to consider the different forms from the standpoint of degree and cause.

In acute attacks of complete retention, generally spoken of as spasmodic, such as occur after operations, or in cases of fever or shock, it is simply necessary to insert a soft-rubber catheter into the bladder and draw off what we estimate to be two thirds of the urine present. If, then, hot applications are made over the pubes, the patient will probably be able to pass urine after an hour without difficulty. If he can not, he should be again catheterized at the end of five hours, and again every five hours, until he is able to urinate voluntarily.

In chronic complete retention due to paralysis, such as occurs in cases of transverse myelitis, the patient should be catheterized every six hours, care being taken at first not to empty the bladder.

In chronic complete retention due to obstruction, the treatment should be the same as in chronic cases due to paralysis, if this is possible. That is to say, a clean, soft-rubber catheter should be passed into the bladder every six hours and the urine drawn off. These cases are, however, almost always due to hypertrophy of the prostate, so that we should be obliged to use an elbowed soft-rubber or woven catheter. In such cases pain, irritation, and tenesmus are often so great that the catheter may have to be passed more frequently in order to give the patient relief. Internal urinary antiseptics, bladder irrigations of antiseptic solutions by means of the catheter, and, if spasmodic, the mouth or rectum should be given.

(Radical cure by means of enucleation or the Bottini operation may be resorted to.)

In chronic incomplete retention due to paralysis, the bladder wall is partially paralyzed, residual urine is present, and cystitis is liable to occur. Here the bladder should be catheterized once or twice a day, and a urinary antiseptic given internally. If cystitis is present in addition to this, we should wash out the bladder every day or two through the catheter with some antiseptic solution.

In chronic partial retention due to obstruction we have a very common condition, such as is usually seen in cases of enlarged prostate or tight stricture where residual urine is present. The treatment of the bladder in these cases should depend very much upon the amount of residual urine and the presence or absence of cystitis. If there is very little residual urine, and no cystitis, we should not pay much attention to the bladder, but should try to treat the cause. Strictures should be dilated if possible, and if they do not dilate they should be cut. Enlarged prostate may also be operated upon if the patient's kidneys are in good condition.

Acute attacks of retention, occurring in cases of chronic incomplete retention due to obstruction, are those most commonly encountered. They occur in men suffering from stricture or enlarged prostate, and are usually caused by cold or by excesses in eating and drinking. Here the patient suddenly finds that he can not urinate, although he has been able to pass a fair amount at frequent intervals for some time past.

This is a critical moment for him, as it is often here that his future woes begin. A case in this condition should be handled with the greatest care, as the bladder, and perhaps the ureters and the pelves of the kidneys are more or less distended or congested and in a favorable condition to be infected by catheterization.

There are also other dangers in relieving this first retention, or subsequent ones—viz., laceration, wounding or bruising of the urethra, production of a false passage by digging into the side of the stricture or into the prostate with hard and badly formed instruments, supercongestion of the urinary tract due to the engorgement of the blood-vessels after the bladder has collapsed, and afterward, perhaps fever and uremia due to septic infection and urinary absorption.

What, then, should be done in these cases to insure the safety of our patient and relieve the symptoms, at the same time exposing him to the least amount of danger? It appears to me that certain points are indicated—viz.: First, use palliative means; second, try to relieve him by harmless urethral instrumentation; third, if this fails, aspirate the bladder, and then again resort to palliatives until the congestion and edema have sufficiently subsided to allow him to urinate or to permit the passage of instruments.

Palliative means consist in giving the patient a hot sitz bath and a rectal irrigation of hot water. If this

does not stimulate the flow of urine an attempt should be made to pass the catheter. If this fails, the patient should be put to bed, with hot poultices over the pubes and perinaeum, and morphine should be given hypodermically. He should not be allowed to remain long in this position—not over two hours—as during this time the damaging influences of retention are going on. Catheter interference should then be resorted to again.

Catheter interference means a great deal, and it is by this means that infection is most often introduced into the bladder, in case it is not already infected, as there is no time when it is riper for it than at this moment of distention. The surgeon should therefore select with the greatest care the catheters to be used, and see that they as well as the lubricants are sterile. The hands of the operator and the genitals of the patient should also be as clean as possible, as this is an important surgical procedure for the patient, although it seems to be so simple to the practitioner.

In choosing the catheters they should be considered in this way: First, soft-rubber; second, woven, or gum elastic; third, metal. Of these, the soft rubber are the best and least irritating, as they are smooth and yielding, tending to follow the curves of the urethra and to slide over the prostatic hillock in case it is enlarged. There are two forms of these catheters, the straight and those with a bend near the end known as the elbow variety.

In the woven catheters, we have the straight, which taper toward the end, where they expand slightly to make a small rounded point, called the olivary tip, and the elbow variety above referred to.

If the retention is due to stricture, we should first try to insert a soft-rubber catheter. If this fails to pass, we should then try one of the woven variety with an olivary tip. These, of a small size, when well made, are very pliable, unirritating, and capable of passing through almost any stricture. If we do not succeed in passing one at first, it is well to inject a little warm oil into the urethra and then try again. If successful, we draw off what we estimate to be two thirds of the urine, and then put the patient to bed with hot applications over the pubes and perinaeum, and direct him to try to urinate again in an hour or two, when he will usually be successful in voiding some urine.

In cases of prostatic hypertrophy, we generally find a so-called middle lobe protruding into the urethra. Here we should use a soft rubber catheter if it will pass; and if we find that a straight one meets with resistance, we should not try to force it, but should instead try one of the elbow variety. These soft-rubber elbow catheters are very finely finished instruments, with a slightly turned up end. When this end reaches the prostate, the slant of the instrument corresponds with that of the gland, so that when it is pushed, it runs up over the lobe into the bladder. In some cases the prostatic urethra is tortuous, owing to enlarged middle lobes, and the middle lobe so enlarged that we must use a catheter with a

double bend in the end in order to enter, as with such a construction one bend adapts itself to the hillock and the other tilts it up still farther. These double-elbowed catheters have to be of the woven variety, as the rubber is not of firm enough consistence. Metal catheters can sometimes be passed in prostatic cases when softer instruments can not. They are not advisable, however, as they require force to make them enter and are apt to damage the tissues.

There is another variety of *stiff* woven catheters containing a stylet, which often enables the physician to pass the obstruction. It is done in this way: When the end of the catheter strikes the prostate the stylet is pulled out, which tilts up the end sufficiently to ride over the obstruction into the neck of the bladder. These catheters, however, are usually poorly made, hard, quite unyielding, and capable of doing considerable damage even in experienced hands. I do not recommend or advocate them. The soft-rubber and woven catheters are the best.

If a gum-elastic catheter can not be made to enter, a filiform should be tried, and if we are successful in passing this into the bladder and some urine escapes by its side, it may be left in place in the hope that the urine may drain off in this way; or, a metal tunneled catheter may be forced over it into the bladder, thus allowing as much of the urine to be drawn off as we desire. I do not advocate this latter procedure, however, unless it is considered desirable to operate immediately afterward.

It seems to me that in such a condition, whether a filiform has been introduced or not, if the patient can not pass his urine that there are but two things to do. One is to perform paracentesis, and the other to do a radical operation.

If paracentesis is performed, and what the surgeon estimated to be two thirds or three fourths of the urine is drawn off, it is probable that by keeping the patient in bed and resorting to the palliative methods already referred to, he will be able to urinate again in a few hours, if even in small quantities.

Of course, in a stricture of such a size that a filiform has to be resorted to, an operation is imperative, but, if possible, it should be postponed until the acute attack has passed, as the results are then better. A surgeon should always try to perform a perineal section on a guide, and for this reason it is advisable if possible to wait until the congestion about a stricture has sufficiently subsided to allow a filiform to be introduced over which a metallic guide can be passed. The strictures causing retention are generally tight ones, situated in the deep urethra, from five to six inches and a half from the meatus, and are frequently associated with false passages. My favorite method of operating in these cases is to introduce a Maisonneuve either with or without a guide, and cutting through the stricture by this means, after which I pass in a large sized guide and perform

an external urethrotomy upon it. This gives us a good smooth urethra, free from the hillocks that we occasionally find after an external urethrotomy alone has been performed, and besides this, there is not so much danger of wounding the bulb of the urethra. If a guide can not be introduced, the operation must be performed without one, but this is rarely the case if the surgeon treats his patient in a conservative way.

The question of radical cure of hypertrophy of the prostate does not enter into the question of an acute attack of retention occurring in case of chronic incomplete retention, as a surgeon would never think of performing an operation upon the gland for the sake of relieving the retention, as he might in a case where the obstruction was due to stricture. He might perform paracentesis at times, but he would go no further unless the attacks of retention were very frequent, the pain and frequency of urination so great, and the condition of the urine so bad that an operation was considered imperative. In this case the surgeon would have to choose between the Bottini method and prostatectomy. From my own personal experience I am free to say that I prefer the former, and under an anæsthetic and performed carefully, I think that it can be classed as a safe operation.

The Treatment of Other Conditions causing Obstruction.—The other obstructive causes that I have mentioned should be treated accordingly. A pedunculated tumor should be removed by a suprapubic cystotomy. A vesical calculus should be crushed by litholapaxy. In case a calculus is in the urethra, it should be pulled forward: if near the meatus, by means of an alligator forceps; or, if near the bladder, it should be pushed back by a sound. If it can neither be pushed backward nor pulled forward, it should be removed through a urethral incision and the wound then sewed up again. In such a case a perineal section should be performed for drainage. Displaced and fractured pelvic bones should be repaired by whatever means are indicated. In case of atresia or an impervious urethra at a certain point, the narrowing should be cut up to the same size as the remainder of the canal.

Extravasation of urine, due to whatsoever cause, giving rise to obstruction, should be treated by a perineal section and drainage, and by making incision into the tissues of sufficient size to allow the exudate to drain away. Abscesses should be treated in the same way.

In considering the palliative treatment of retention the question of catheterization and paracentesis have been frequently dealt with, and it seems to me that it might be well to say a few words on these two procedures.

The question of how to keep catheters clean was for a long time a puzzling one, but of late it has been much simplified by an improvement in the variety of catheters and the introduction of formaldehyde as a disinfectant.

I will briefly outline the methods pursued in my clinic and private practice.

Soft-rubber catheters should be washed, flushed out with hot water, by injecting in through them by means of a syringe, boiled for five or ten minutes, then dried with a sterilized towel, and afterward kept wrapped up separately in a towel or else stretched out upon it, or on a clean glass shelf.

Metal catheters and all other solid urethral instruments should be washed, wiped, and then boiled for five or ten minutes in either plain water or sodium solution.

Woven catheters of some *superior* makes can be boiled for five minutes in many cases on several different occasions without injury. This is, however, not safe, as it tends to melt the varnish with which they are made, thus making them brittle, and denuding them in places, or else leaving them in a sticky condition. They should be washed with soap and water, flushed out with warm water, dried with a sterilized towel, and then disinfected in a formalin sterilizer. Schering's formalin sterilizer is the one used.

It is a tin box, japanned on the outside, eighteen inches wide, eleven inches and a half high, and eight deep. It has three shelves of wire netting on which to place instruments, and a small compartment for the formalin lamp. A door opens in front, the size of which corresponds to the side of the sterilizer.

The method of disinfection is by means of the paraform pastilles. Paraform is polymerized formaldehyde and occurs as a light white powder, which can by means of heat be entirely converted into formaldehyde gas. It can be purchased in the form of pastilles of five to fifteen grains each. Formalin is a forty-per-cent. solution of formaldehyde.

The method of doing this in our sterilizer is as follows: The instruments are to be placed upon the wire shelves. A five-grain paraform pastille is to be put into the lower receptacle of the lamp (the upper cup is not to be used with the sterilizer), the lamp lighted, and the door closed. There is a small glass window in the door to allow the flame of the lamp to be seen. The outlet on the top of the sterilizer will facilitate the escape of the gas when the process is complete. The lamp will burn for twenty minutes in the air of the sterilizer, if empty, and only about five minutes are required for the entire vaporization of a five-grain paraform pastille placed in the lower cup.

Ten minutes' exposure to this gas in the amount obtained by the vaporization of a five-grain pastille will kill anthrax, tubercle, diphtheria, and typhoid germs, and streptococcus, staphylococcus, *Bacterium coli commune*, etc.

Aspiration.—When a catheter can not be made to enter the bladder, and a radical operation is not considered wise, paracentesis should be performed either through the rectum or over the pubes. This procedure is not without danger, as in the first case we are liable to

have a rectovesical fistula following, and in the second we may have an abscess in Retzius's space, or a general peritonitis.

Of the two operations, I believe that the suprapubic route is the preferable one. The point for the introduction of the instrument should be in the median line, just above the symphysis. The trocar should be pushed inward and downward for about three inches, and the stylet should then be withdrawn until what we estimate to be two thirds of the urine in the bladder has escaped. A piece of plaster should then be placed over the hole, and the patient put to bed.

Neither by catheterism nor by paracentesis should all the urine be drawn off from a patient's bladder, as fatal syncope has resulted from such a procedure.

Aside from this, the sudden emptying of the bladder produces a collapse of the distended urinary tract and a consequent engorgement of its surface. Within a few days the urine contains a little blood independent of mechanical injury; it becomes turbid and scanty; the temperature rises, the tongue becomes dry and brown, the mind unsettled, and the patient sinks into the condition known as typhoid. He becomes septic from urinary absorption; his kidneys become congested, resulting in uræmia and death.

In all cases of chronic, incomplete retention the treatment of the inflamed and atonic wall of the bladder is to be considered. A patient may live for years with a chronic cystitis, if his bladder is treated properly. This trouble is generally not curable, but few inflammatory conditions yield results to treatment more gratifying to both the physician and the patient.

The methods of toning up an atonic bladder are, by using remedies which will excite contraction of the bladder wall, such as strychnine, cold sponging, or douching over pubes, and counterirritation to the spine.

Civiale recommended cold-water injection into the bladder, beginning with tepid water and gradually decreasing the temperature to 60° F. This should be done after emptying the bladder. Two or three of these injections can be given one after another. These generally excite contractions, which once having begun will bring about favorable results. Two injections daily for a fortnight will usually cause marked improvement.

The faradaic current given by placing one pole over the lumbar or hypogastric region, and introducing the other into the bladder by an elastic bougie with a metallic tip, is often of great service. This should be moved around until it comes in contact with the different parts of the bladder wall for five minutes at a sitting. Various preparations, such as those of iron, strychnine, and other tonics, are recommended by different practitioners.

Prognosis.—The prognosis of atony and paralysis of the bladder depends upon the cause. In cases of spinal and cerebral lesions, if they are incurable, the local condition will not improve. In obstructive cases it is different.

In atony due to stricture, if this is cured, the bladder wall may be expected to regain its tone under appropriate treatment. In prostatic cases, however, the result is often not so favorable, on account of the age of the patient.

In all cases of paralysis or atony early attention to the condition of the bladder is of great importance, as the longer the urine is allowed to remain in contact with mucous membrane lining it, the more likely it is to excite disease; while the frequent and continued distention of the muscular fibres gradually renders them thinner, and diminishes their chance of ever being able to be restored to a healthy state by any treatment that can be employed.

23 WEST FIFTY-THIRD STREET.

INHIBITION.

By S. J. MELTZER, M. D.

(Concluded from page 703.)

As to the nature of inhibition, I shall briefly mention here only the one theory which was put forward and ably supported by Hering, Gaskell, and Biedermann, and which has already gained quite a firm hold. Hering has extended his theory of the perception of colors to all living tissue. There are in all living tissues, Hering assumes, two antagonistic chemical processes: assimilation and dissimilation, the building up of the tissue and its destruction. Any stimulus can affect the tissue either by increasing the dissimilation, which manifests itself, for instance, as a contraction, or it facilitates assimilation, which is then inhibition. Gaskell terms the antagonistic processes anabolism and catabolism.

Looking over the gradual development and growth of our knowledge of the inhibitory phenomena, we notice, in the first place, that the observations on the presence of inhibition were first made in organs or functions which are normally in a rhythmic, or arrhythmic, or tonic state of activity: in the rhythmically contracting blood and lymph hearts, in the rhythmic movements of respiration, in the arrhythmic peristalsis, and in the tonus of the blood-vessels. Inhibition simply presupposes preceding activity. In the resting, relaxed skeletal muscle inhibition can not manifest its presence. Nor can it be easily recognized in a muscle which is made to contract by a peripheral or reflex stimulus, because such a stimulus obviously favors contraction, and not inhibition. It has therefore been a very tedious task to establish unquestionable instances of reflex inhibition in the muscles usually at rest, and by methods usually employed to bring out reflex contractions. The situation, however, in my opinion, is strikingly changed since Sherrington discovered the condition which he terms "decebrate rigidity." The skeletal muscles are in a pronounced state of contraction, and a peripheral stimu-

lus brings out inhibition easily. Our usual conception with regard to the natural effect of a stimulus will undergo a change; reflex inhibition will henceforth stand on an equal footing with reflex contraction.

Another circumstance which has facilitated the establishment of inhibition phenomena is the occurrence of such nerve trunks as contain exclusively or prevalently inhibitory nerve fibres. The discoveries of the inhibitory effects of the vagus, the chorda, the splanchnic, and the laryngeal superior nerves preceded the discovery of other inhibitory phenomena, especially those of the reflex-inhibition variety. Without the inhibitory nerves the phenomena of reflex inhibition could hardly have been properly interpreted. We must, however, bear in mind that the discovery of the cardio-inhibition was made on the vagus of the frog, which contains also the augmentator nerve fibres, and that the inhibitory effect of the stimulation in this case is not so much the result of the presence of the inhibitory fibres in the nerve trunk in greater numbers, but is due mainly to the circumstance that when the augmentator and inhibitory nerve fibres are stimulated together the inhibitory effect prevails (Bowditch (133), Baxt (134)). This predominance, however, is not a special quality of inhibition; for if the chorda—which is the inhibitory nerve for the blood-vessels of the submaxillary gland—and the sympathetic are stimulated together, the result is not much different from what it is when the sympathetic alone is being stimulated. The predominance of one kind of an effect varies with the different organs, and is rather a part of the special mechanism in each organ than an inherent property of the inhibitory or the motor nerve. We may therefore say that the discovery was due to the accidental circumstance that, in the heart, inhibition is the ruling power.

The augmentator-nerve fibres have a long after-effect, and the cardio-inhibitory nerve fibre possesses only a short after-effect. When both nerve fibres are stimulated together the inhibition prevails during stimulation, but the augmentation is not destroyed or even affected. Therefore, when the stimulation is interrupted and the short after-effect of inhibition vanished, the long after-effect of the augmentator appears on the scene and runs its natural course. It was partly by the appearance of the long after-effect that the presence of the augmentor fibres in the vagus of the frog was recognized. The length of the after-effect, too, is not an integral property of either augmentation or inhibition; in the mechanism of the submaxillary gland it is the chorda which possesses the long after-effects, and this is revealed after the creation of the simultaneous stimulation. Let us add further that there are also differences in the lengths of the latent periods between the motor and the inhibitory nerves, which also vary with the mechanisms, and that the predominance of one kind of an effect over the other in a simultaneous stimulation is, after all, as has been shown by me (135) and by Hunt

(136), nothing but a resultant more or less in favor of one or the other of the two opposing factors.

Now there can be no doubt that in by far the most of the nerve trunks both kinds of nerve fibres are combined in all sorts of proportions and relations; and when we bear in mind that all our stimulations always mean a simultaneous stimulation of both nerves, what a variety of results we have to expect! But let us take up only this one possibility. Let us suppose that the motor nerve of a skeletal muscle contains motor and inhibitory fibres which possess exactly the same relations as we have seen actually to exist in the vaso-motor mechanism of the submaxillary gland—*i. e.*, the inhibitory nerve has a long and the motor nerve a short after-effect, and when both nerve fibres are stimulated together the motor effect will prevail, while there will be an inhibitory effect after cessation of stimulation. Now, what, under these circumstances, would be the effect of the stimulation of such a motor nerve? Exactly that which really takes place: soon after stimulation a contraction will follow, and after cessation of the stimulus a more or less rapid relaxation will take place. What proof have we against such a supposition? None.

Our knowledge of the laws of life had a one-sided development. The active manifestations of life aroused our curiosity; the phenomena of contraction, secretion, sensation presented problems and were studied. The absence of these phenomena was no problem. Rest of a muscle did not require an explanation. A muscle is at rest, it was implicitly assumed, when there is no cause for its contraction. Thus all the laws and conceptions which were formulated upon this one-sided basis are obstacles to the progress of the conception of inhibition. Had there been more such unbiased minds as that of Charles Bell, to whom vital arrangement for an active relaxation of the muscle was a self-understood requirement, inhibition would have been firmly established long ago. Or if an accident had only put into the hands of the earlier experimenters animals with “decrebrate rigidity,” inhibition would not have had such an uphill road to travel. Or if a criterion could have been found which would with certainty distinguish inhibition from its active opponent, the study of inhibition would have been an easier task. Fatigue, degeneration, regeneration, cold and heat, character of stimuli, responsiveness, poisoning with atropine, muscarine, physostigmine, etc., have helped in one or the other case to shed light on certain questions; but, so far, neither of these conditions and effects have been proved to possess a constant relation to either of the antagonistic phenomena.

All these difficulties and obstacles notwithstanding, inhibition can now, at its somewhat belated golden jubilee, look with satisfaction upon the long list of phenomena which have been gradually and laboriously gathered from all the provinces of life. In our record

we have seen that inhibition can be found in all the forms in which life makes itself manifest: motion, secretion, and sensation. We have found it present in all the irritable tissues of the body, plain and striated muscle, nerve cell, nerve, and epithelial cell. We have found it represented in nearly all the peripheral and central organs and functions of the body. Inhibition can be brought out by all kinds of stimuli applied to the skin, viscera, the peripheral or central end of a cut nerve, the subcortical and cortical centres of the central nervous system; and it is manifestly present in the voluntary and the involuntary activities of the living organism.

General Conclusions.—In the face of this ubiquity of inhibition, and in consideration of the manifold experience we have gathered with regard to its actual complicity in the manifestations of life, we are justified, it seems to me, in drawing the following fundamental conclusions:

1. Inhibition extends as far as the existence of irritability, and is an integral part of it. All irritable tissues of the living body respond to a stimulus with a specific activity, as well as with an inhibition of this activity; the actual effect of a stimulation is always only a resultant of the two opposing factors, but mostly, perhaps, with a greater leaning toward one or the other, according to external circumstances. Neither the impulse of activity nor that of inhibition is wiped out; they often run out their course in a manner imperceptible to us.

2. All the actual phenomena of life are not the pure manifestations of one of these factors, but are the resultants of the two antagonistic forces; there is no absolute rest in a living part, and there is no action without any admixture of inhibition. The state of life in each part of the body depends upon the general relations between the two antagonistic forces in the entire body, and upon the special relations existing in this special part. All admitted biological laws which have been formulated under the presupposition that they were being derived from a study of the behavior of the pure activity will have to be revised.

3. In the peripheral as well as in the central organs activity and inhibition are apparently separately accessible by special nerve fibres, of which the government of the body is making use in such a purposeful manner as to cause a required degree of inhibition of a part, the antagonist of which is ordered to action.

I believe that in my estimation of the extent and importance of inhibition I am, at least to a great extent, in accordance with those two eminent physiologists, Gaskell in England and Boedermann in Germany.

I am convinced that the dualistic conception of the phenomena of life is destined to make a profound impression upon medicine and therapeutics; and I am also profoundly impressed with the fact that the discovery and development of inhibition are among the greatest achievements in biology of the dying century.

A LITTLE POINT OF GREAT IMPORTANCE IN TRANSFUSION.

By LOUIS JULIAN Y GENELLA, M. D.

NEW ORLEANS.

THE principal fear in transfusion seems to be the introduction of air. Ought this ever to occur? If the following method is adopted I do not think it is possible:

Cut down to the vein with the usual precautions and place three ligatures around it; the one farthest from the heart tie tightly around the vein. About half an inch above is passed the next ligature around the vein, but do not tie. Next put another ligature about three quarters of an inch above this second ligature and tie it tightly, but as a slipknot—i. e., tie by pulling on A (1, 2) and B (2), and when it is needed to untie pull on A (1) and A (2).

Make a free incision between ligature No. 1 and No. 2, and introduce the needle with the saline solution running at once so that it will pass under ligature No. 2.

As ligature No. 3 [A (1, 2) and B (2)] is tied, the fluid will flow out around the sides of the incision, thus washing out any air that could have got into the vein. While the fluid is still running tie ligature No. 2 around the instrument, and by pulling on A (1) and A (2) of No. 3 we again open the venous channel without danger of letting in any air.

LANDRY'S PARALYSIS.*

By W. H. HAYNES, M. D.

BROOKLYN.

THE disease known as Landry's paralysis may be considered, according to our present knowledge, as an infectious disease of the nervous system. Although no specific germ for it has as yet been isolated, others, such as the *Streptococcus longus* and the *Staphylococcus pyogenes aureus* and *cereus*, have been found in some cases, and it is accompanied, as are all infections, by an enlarged and softened spleen and enlarged mesenteric lymphatic glands. It affects mainly the anterior horns of gray matter of the cord, or at least the ganglion cells, though the white matter and efferent motor nerves are also involved. In some cases it is attended by more or less constitutional symptoms, such as we see in the different forms of severity of anterior poliomyelitis, may be ascending or descending, lasts from a few days to fourteen weeks, and its typical condition is one of flaccid paralysis of all the extremities, with loss of reflexes, little disturbance of sensibility, normal electrical reactions, sphincters uninvolved, rapid course, and universal fatality. This summary is the result of a study of forty-seven cases and the most recent literature on the subject. Such being its aetiology, pathology, symptomatology, and course, so far as at present determined, we turn to the more practical part of the subject, that of diagnosis and treatment.

The diagnosis of this form of sudden paralysis is attended by much difficulty, and in the study of the cases reported one gets easily confused by finding cases of multiple neuritis, acute poliomyelitis of adults and children, and polioencephalitis reported as cases of this disease. And even with the history and pathological findings the diagnosis is sometimes in doubt, as all these affections are coming to be considered of an infectious nature, and we are finding lesions of a similar character in the different parts affected. Still, ordinarily, we can usually distinguish the following diseases with which it may be confounded—namely, multiple neuritis, transverse myelitis, diffuse myelitis, disseminated myelitis, meningomyelitis, anterior poliomyelitis, and polioencephalitis—chiefly by the difference in the history, onset, course, and limit of the parts affected, in involvement of sensibility and the sphincters, and in results.

In multiple neuritis we have the history of the ingestion of some poison or a preceding acute infectious disease; though the onset is sudden, the course is slow, sensibility is involved, electrical reactions are lost, atrophy is present, it is without fatal issue, and results in cure after a tedious convalescence.

In transverse myelitis there is usually a history of an injury; pressure, preceding infection or syphilis, is localized, sensibility and the sphincters are involved, and there are atrophy and electrical changes.

* Read before the Brooklyn Pathological Society, April, 1899.

In diffuse myelitis there is a more wholesale presence of like constitutional and spinal symptoms to the foregoing, while in the disseminated form the spinal symptoms are the same, only scattered, according to the different foci involved.

In meningomyelitis there are early presence of muscular spasm, pain, fever, and other marked constitutional symptoms, and those of a meningitis preceding the development of the paralysis, together with cerebral symptoms in the cerebro-spinal form.

In the ordinary form of anterior poliomyelitis, as we see it in children and adults, chiefly by the limitation of the paralysis to certain groups of muscles, and in polioencephalitis, the cortex and cranial centres are implicated; while Landry's paralysis, as a rule, never involves more than the efferent spinal motor nerves, the anterior horns of gray matter of the cord, and the medulla. It is an exudative inflammation with cellular infiltration of the circumvascular sheaths, degeneration of the ganglion cells, and loss of structural elements, with or without degeneration of the anterior roots.

As a method of treatment (which, however, has thus far been universally unsuccessful), I could suggest, besides the use of the usual constitutional remedies, the trial of the antistreptococcic serum of Marmorek. I am prompted to make this suggestion by reading the results of the experiments of Homen, of the University of Finland, and his pupils, who experimentally infected animals with streptococcic bacteria and their toxins, and the resulting changes in the nervous system were strikingly similar to those found in Landry's paralysis, and also by the favorable results of its use in other forms of this infection, notably in erysipelas and those following the puerperium.

ANTISTREPTOCOCCIC SERUM IN PUERPERAL SEPTICÆMIA AND PELVIC CELLULITIS.

By A. G. DEARDORFF, M.D.,

SAN FRANCISCO.

HAVING recently had some experience in the use of antistreptococcic serum, I feel impelled to report two cases in which this promising remedy acquitted itself admirably. As a result I have been led to believe that we have now in this agent a specific for puerperal and other infections, and that its field of usefulness will steadily widen.

CASE I.—On January 2, 1899, Dr. T. was called to attend a case of abortion, occurring before the third month. The uterus was emptied without difficulty, and the case progressed favorably until the fourth day, when a chill occurred, followed by a rise in temperature and pulsé rate, with a dry, brown-coated tongue, tenderness over both inguinal regions, and tympanitis, indicating, of course, a peritonitis, more or less circumscribed. The pulse rate ranged from 106 to 120 and the temperature from 101° to 104° F. For a time the patient appeared to do well under the usual treatment with good nursing, and convalescence seemed to be imminent. But the fever continued until January 16th, when it was decided to curette and irrigate under chloroform, which I assisted the attending physician to do. We found no *débris* within the uterine cavity, yet the fever continued, with nausea, loss of appetite, and tympanitis. On January 25th, nine days after the curetting, and a little over three weeks after the abortion, the thermometer registered 102.5° F. and the pulse rate was 115. While the symptoms did not indicate immediate danger, the stubborn character of the case caused us considerable anxiety. At that time a trial of antistreptococcic serum was considered, and accordingly, at 11 A. M., we administered thirty drops of the serum made by Parke, Davis, & Co.

At 2 P. M. the skin, which had been hot and dry, became moist. The temperature had fallen to 99.4° F., and the patient was sleeping quietly; she also rested well during the succeeding night. During the two days following the temperature remained normal, except on the night of the 27th, when there was a slight rise. A second administration of thirty drops of the serum on the morning of the 28th caused a decline to the normal temperature, from which time forward the patient convalesced uninterruptedly.

To me this was a most remarkable result. But, in looking over the history of the case, I am inclined to think it would have been better treatment to have repeated the injection at shorter intervals, although the effect of the first dose was so decided that it was not considered necessary to do so.

On January 24th a case of inflammation of the left ovary and tube presented itself to me. On examination, a swelling as large as an orange was revealed to the left of the uterus, which was very painful on pressure. There was evidence of gonorrhœal infection, and I therefore placed the patient in the hospital under the care of a nurse. At the time of her admission the temperature was 101° F. and the pulse 100; the tongue was coated. Despite the most careful treatment for three days, the patient's condition gradually grew so much worse that I was obliged to resort to morphine to secure rest. The swelling remained, and gave every indication that a pus cavity was forming. Having had so much success in the case previously referred to, I thought the serum might act well in this one also. At 9.30 A. M., on January 27th, I administered thirty drops of antistreptococcic serum (Parke, Davis, & Co.). The patient's temperature registered 102.5° F., and remained at this point until 2 P. M., although there had not been sufficient pain to require the use of opium since the previous midnight. I considered the serum a failure in this instance, and immediately gave five grains of phenacetine. The temperature dropped two degrees, but rose again to 102° F. at 5 P. M. The tongue, however, was moist, and the pain was not unbearable.

At 7.30 P. M. the serum began to manifest its effect.

The patient perspired profusely during the night and slept well. On the following morning the temperature reached the normal, the pulse rate had declined to 75, and the tongue was moist and clearing. To my great surprise, upon making a pelvic examination, I found that the swelling had been reduced to a third of its former size, and but little soreness remained. The patient at once began to eat well, and made a quick recovery, leaving the hospital a week later. This was one of those cases which ordinarily require at least two or three weeks' treatment, and often an operation to get them well. Under the serum treatment the abscess disappeared in forty-eight hours.

CASE II.—On April 5, 1899, I was called to a case of labor at full term. The surroundings were of the very worst—dusty rooms in a basement, dirty bed and bedding. The first stage was about over when I called. I hastily made preparation for the woman's delivery, which soon occurred, and without a nurse, only an elderly lady for my assistant. I took all precautions possible for cleanliness, but to no avail, as on the 8th, or the third day following delivery, she had a chill. The temperature a short time after was 103.5° F., pulse 125, and so profound was the poison that the patient was in a stupor, and there was every evidence of severe puerperal fever. I immediately irrigated the uterus with lysol water, but found nothing in the organ in the nature of retained placenta. I did, however, find a fermented condition of the lochia. I administered the first day sixty minims of antistreptococcus serum. In a few hours profuse perspiration came on. The temperature fell by midnight to 101° and the pulse to 100. The next morning I again administered sixty minims of serum. The temperature rose after a second slight chill to 102°, and the pulse to 115, but for only a few hours, when the temperature fell to 100°. In the evening of the second day I administered sixty minims of serum, and I then had my case completely under control. On the morning of the third day of the fever the pulse was 80, the temperature 99.8°, and she had begun to improve, having slight returns of fever, but by administering thirty or forty drops of serum, as the fever came on for three or four days, it was checked. I would not under any circumstances be without antistreptococcus serum in puerperal troubles, and in any and all blood poisonings I feel we have a wonderful help in its action.

There is a wide field for the employment of antistreptococcus serum in all inflammations of a septic nature, and from my experience I can affirm that its action is rapid and sure. I have used it in certain bad cases of tuberculosis, exhibiting pus in the sputum, always with marked benefit. Other physicians in this city have used it successfully in the treatment of cases of puerperal fever, in which the older means of treatment had failed and the patients had been given up to die.

The dose generally recommended is larger than those which I used, but I consider thirty drops, often repeated, better than a larger dose; at least, my small doses did all that was necessary to be done.

The Seaboard Medical Association, of Virginia and North Carolina.—The president, Dr. Lucien Lofton, announces that the next meeting will be held in Newport News, Virginia, in January, 1900.

Therapeutical Notes.

A Paste for Trichophytosis Barbæ.—Dr. Menahem Hodara, of Constantinople (*Monatshefte für praktische Dermatologie*, May 1st), has made considerable use of the following formula:

R Lanolin, $\frac{1}{2}$ each	20 parts;
Vaseline, $\frac{1}{2}$	
Glycerin	10 "
Sugar	20 "
Sulphur	10 "
Zinc oxide	20 "

M.

He has employed the paste satisfactorily in various skin diseases, but finds it particularly effective in the treatment of sycois. It is applied in a thick layer night and morning. When the pustules have fully dried up and the crusts have all been removed, it is sufficient to apply it at night only.

Arsenic as a Corrigent of Thyreoid Medication.—*Lyon médical* for April 23d cites Dr. Léon Mabilie, of Reims, as having found that Foyler's solution, in daily amounts of from five to fifteen drops, prevents the tachycardia, the nervous derangements, and the loss of flesh that are apt to be occasioned by the thyreoid medication.

The Administration of Creosote.—The *Gazette hebdomadaire de médecine et de chirurgie* for April 23d attributes the following formula to Kopp:

R Beech creosote, $\frac{1}{2}$ each	1 part;
Benzoin, $\frac{1}{2}$	
Powdered charcoal	6 parts.

Powder the benzoïn, triturate it for a few minutes with the creosote, and add the charcoal gradually. This powder is said not to soil paper. It is to be taken in wafers.

Pills for Ovarian Neuralgia.—The *Medicinisch-chirurgisches Central-Blatt* for April 14th publishes this formula as J. S. Martin's:

R Extract of belladonna	33 grains;
Extract of stramonium	43 "
Lactophenine	90 "

M. Divide into twenty pills. Two or three to be taken daily.

Baccelli's Powders for Influenza.—In cases in which the fever and the nervous symptoms are severe Baccelli (*Gazzetta degli ospedali e delle cliniche*, 1898, No. 43; *Centralblatt für innere Medizin*, 1898, No. 38; *Medicinisch-chirurgisches Central-Blatt*, April 21st) recommends the following formula:

R Quinine salicylate	3 grains;
Phenacetine	24 "
Camphor	$\frac{1}{10}$ of a grain

M. Six such powders may be taken in twenty-four hours.

An Antiseptic Suppository.—According to the *Riforma medica* for May 3d, Wasshew recommends the following:

R Pyocetanin	$\frac{1}{10}$ grain.
Extract of belladonna	10 "
Cacao butter	30 grains

M.

For one suppository.

THE
NEW YORK MEDICAL JOURNAL.

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 27, 1899.

THE AMERICAN MEDICAL ASSOCIATION.

THE association, as everybody knows, is soon to hold its annual meeting. It is to be hoped that before the time for the meeting arrives the influential members will have considered certain suggestions that appeared in the May number of our valued contemporary *Medicine*. That journal points out that when the association was organized the great majority of the profession lived in the Middle and Eastern States, so that it was comparatively easy and convenient and inexpensive for the members from all parts to assemble in any city large enough to accommodate them. This long ago ceased to be the case. The medical profession of the United States is now spread over a vast territory, and its plan of holding annual meetings first at one remote point and then at another is not at all in conformity to the theoretically representative character of the organization. It is a hardship for a Pacific coast man, for example, to devote the necessary time and money to a meeting held in the East, and *vice versa*. The busy practitioner can not do it as a rule. The result is that the meetings, when they are held in places far distant from the great mass of population, are too apt to be made up largely of men of leisure so far as the great constituencies are concerned.

Medicine suggests that these defects would be lessened by a division of the association into several large geographical branches which should meet annually at places convenient to themselves, while the entire organization should hold biennial or, better, triennial meetings in some large city near the centre of the territory constituting the United States. Perhaps it would be well to hold the triennial meetings—for we agree that once in three years would be better than once in two—in several central cities in turn, perhaps Chicago, St. Louis, Kansas City, and Omaha. The order of rotation should be settled definitely and never departed from save for some extraordinary reason. We are convinced that some such arrangement would prove beneficial to the association. We must not be understood as imputing all this to *Medicine*; we have simply taken our inspiration from our contemporary.

THE X RAYS IN A NEW LIGHT.

THE *Practitioner* for May contains an article by Mr. Edmund Owen on Fractures—in the New Light, in which he calls attention to the widely increasing use of the X rays by the laity for the purpose of ascertaining the results of surgical intervention in injuries, especially fractures. He begins with the account of a case of a man of fifty-three who was treated in St. Mary's Hospital, London, for a fracture of the right femur just below the lesser trochanter. The utmost difficulty was experienced, in spite of constant care and attention, in keeping the fractured surfaces in apposition, the upper fragment being persistently flexed and adducted; and consolidation, when finally attained, was in a bad position. Five months later the patient again broke the same femur about two inches below the site of the former fracture, but this time the treatment was devoid of difficulty and in every way satisfactory in its result. A skiagram shows the results of the two fractures, in the first of which the deformity is obvious. On this Mr. Owen remarks: "Let us suppose that this man had some ignorant, officious, and interfering friend who had taken him to a radiographer and paid for an X-ray picture of his thigh bone; that they showed the picture to some medical man and asked what he thought of it, and that the medical man said—which he might well do—that he should not care about turning out a broken thigh bone like that! Then let us suppose that a pushing solicitor is asked his advice, and that in due course an eloquent barrister exhibits the thigh bone and its treatment in all their nakedness, as it were, to a sympathetic jury—it might be of little avail that I pleaded that I had brought 'a proper degree of skill and care' to bear on the case, and it is not at all improbable that the man would leave the court victorious in an action for malpraxis."

It would appear obvious that with the accessibility of these X rays to the public at large there is a great and real danger that many a patient who may have no real reason to complain of the results attained in his case, which are possibly as perfect as care and skill exercised under adverse circumstances could make them, may yet be moved thereby with excess of pity for himself over some defect resulting from injury of which he would have remained unconscious save for the rays. Still greater is the danger from officious friends, inconsiderate or malicious *confrères*, and shyster lawyers.

It is evident, therefore, that it behooves practitioners to recognize and prepare to meet this new menace—for even though an action for malpractice fail, who

shall repay the practitioner for the worry, anxiety, and loss of time and practice entailed, or reimburse him for the expense? Mr. Owen suggests as precautions to minimize this danger: 1. A thorough and careful examination under an anæsthetic whenever inspection is at all wanting in decisive clearness of the information it affords. 2. A consultation whenever there is the least uncertainty. 3. If necessary, the practitioner should urge resort to a skiagrapher by the surgeon before dealing with the injury, instead of risking a surreptitious visit to one subsequently with the X ray as the surgeon's enemy instead of as his ally.

This latter course, however, owing to the injuries which have from time to time followed the application of the X ray, is not altogether free from the possibility of adding dangers of its own, and so may increase the physician's burdens instead of mitigating them. The X ray may thus prove doubly a traitor.

The author accordingly caps his advice with a recommendation that every practitioner should become a member of the Medical Defense Union, an association in England which investigates all charges of a professional character brought, or threatened to be brought, against any of its members, and if it finds the physician's case worthy of support takes all the worry and expense of his defense off his hands. Further, this society has in many instances, by showing a firm and decided front, upon examination of a physician's case, quashed and rendered abortive threatened proceedings, whether of a blackmailing character or sincere, but unfair and misjudging. It would be a good thing if every State in this Union should form such a defense league. In most States the fees need be but small, for the moral support which such an organization would afford would soon bring it to pass that blackmailing suits would have little in them for disreputable lawyers, while those that were the result even of honest conviction would more often than not be reasoned out of further progress.

Mr. Owen's final words express sentiments which can not be too often or too forcibly impressed upon every member of the profession. He says: "Lastly, in connection with the mistakes, failures, or imperfect results turned out by brother practitioners, it is our duty to be extremely charitable, and never to pass a hasty adverse judgment upon their handiwork; for it is just possible that when the case was first seen it was surrounded with difficulties of which at that time we can know nothing, and that the care and skill bestowed on it were worthy of a better issue. To judge merely by a result may be equally unfair and uncharitable."

THE ALLEGED CONTAGIOUSNESS OF LEPROSY.

WE have long been convinced that the doctrine of the contagiousness of leprosy was fallacious, and we have deprecated the newspaper attempts that have been made from time to time to create a panic in the community by dilating on the outrageousness of allowing a leper to remain "at large" in New York. That the great majority of physicians who have properly studied leprosy coincide in this view we have not the slightest doubt. This is shown by their absolute fearlessness in the presence of the disease. For example, for quite a number of years past it has not been a very uncommon thing for a leper to be stripped and examined minutely at a meeting of the New York Dermatological Society. That society's meetings are held, with an occasional exception, at the residence of some one of its members, under the same roof with the wife and children of the member, and yet these clinical demonstrations of leprosy have given rise to no anxiety, and no harm has come of them.

However, all this is negative evidence only, and would be overturned by a single instance in which leprosy was conveyed by contagion. We are using the word contagion, of course, in the sense in which the public understands it, and not as including inoculation, for we do not question that leprosy is inoculable. The difference is very clearly expounded in the *Medical Age* for May 10th, in an article entitled *Leprosy is Most Certainly Not Contagious*, by Dr. Roger S. Chew, late sanitary and chemical analyst to the Calcutta municipal corporation and assistant to the health officer of Calcutta. Dr. Chew describes himself as "a staunch American" and "a very bigoted one," so that he "can not be accused," he says, "of posing as John Bull's apologist" if he denies that the British government was prompted by interested motives when it stood up for the non-contagiousness of leprosy at the Berlin conference.

As regards the treatment of lepers, with the purpose of preventing or restricting the spread of the disease, we favor their segregation, but this does not argue that we are at all wavering in our disbelief in the contagiousness of leprosy, still using the word contagiousness in its popular acceptance. It is no argument, says Dr. Chew, to contend that because Verneuil favors isolation he is dishonest in his profession of belief that the disease is not contagious. "His long experience," Dr. Chew continues, "tells him how prolific lepers are and how they are afflicted with an insatiable sexual hunger. He knows that they are men and women whose natural passions and sentiments of anger, etc., have been aggravated fear-

fully by disease, and that a blow or bite from any one of them will cause the non-contiguity" [non-continuity?] "of surface necessary to inoculation. He knows that isolation—meaning separation of the sexes—precludes the possibility of procreation, and therefore, so I presume, advocates segregation with a view to utterly prevent the transmission per heredity of lepra. He hints as much in his letter to Leloir, and to make it more definite he says leprosy is 'not contagious from man to man.'" There are other interesting points in Dr. Chew's article than those we have touched upon, and we commend it as a whole to those of our readers to whom it may be accessible.

A CLUNSY PIECE OF TOUITING.

AN esteemed correspondent has recently called our attention to an exceedingly "yellow" puff of Dr. John B. Murphy's nitrogen treatment of consumption, in the *Chicago Evening Post* for March 28th. It will be remembered that Dr. Murphy explained his method and set forth his ideas on the subject at last year's meeting of the American Medical Association, in Denver, and, if we are not mistaken, he is to report further upon it at the approaching Columbus meeting of the same body. Soon after the Denver meeting we called attention to the ingenuity of the plan, but expressed our doubts as to its wide applicability. Like all other alleged advances in therapeutics, it will have to stand or fall on the strength of a far more ample experience than it has yet stood the test of. Newspaper puffery will prove of no lasting avail; indeed, it is far more likely to hamper Dr. Murphy in his endeavors to get at the truth in the matter. He is too bright a man not to understand this; hence we decline to believe that, as has been suggested, this horrible article was inspired by him or even prepared with his knowledge. To be sure, the writer professes to quote Dr. Lemke's precise words, but, while we can conceive that an admirer of Dr. Murphy's might let his enthusiasm so far get the better of his judgment as to lead him to consent (while whispering he "would ne'er consent") to the publication of an article comparable in drift to the *Post's*, we can not admit that any man whom Dr. Murphy could tolerate as a professional associate would use such absurd expressions as the article attributes to Dr. Lemke. Whatever may be the merits of the nitrogen treatment, we trust the *Post's* sensational exposition of it will not prejudice the American Medical Association against it; most assuredly it can not impress any right-minded medical man in its favor.

DIONIN AS A CALMATIVE.

THE difficulty of avoiding the use of objectionable narcotics in chronic diseases accompanied by cough, for example, is well recognized and regretted. If there can be found a substitute that is not likely to prove injurious in the long run, a distinct gain will have been made. Dr. G. Schröder (*Therapie der Gegenwart*, 1899; *Centralblatt für innere Medizin*, April 29th) thinks that dionin will be found to answer the purpose. He describes it as a hydrochloride of the ethyl ether of morphine, soluble in ten parts of water, and not offensive

to the taste. The dose is the same as that of codeine, and Schröder finds that it is quite as efficient as that alkaloid in allaying cough and procuring sleep, but not so effective as morphine in cases of actual pain, as in the painful deglutition attendant on tuberculous disease of the larynx. It is said to have no unpleasant effects, but all such statements concerning a new drug must be taken with caution.

THE STANDARDIZATION OF FLUID EXTRACTS, ETC.

WE have received from one of the leading pharmaceutical manufacturing establishments of the country a communication which seems to us a most convincing argument in favor of extending the standardization requirements in the forthcoming revision of the *United States Pharmacopœia* to belladonna, colchicum, conium, gelsemium, hyoscyamus, ipecac, physostigma, podophyllum, stramonium, and veratrum. It seems unnecessary to present the reasons why this is desirable, for we do not doubt that they are recognized by every physician and every pharmacist by whom pharmacology has been adequately studied.

THE CHICAGO BOARD OF HEALTH'S GOOD WORK.

IT appears from figures lately published that the Chicago death-rate has been decreasing steadily for a number of years to such an extent that, whereas the average age of those who died in 1872 was a little over fifteen years, in 1898 it was over twenty-nine years. We do not doubt that this is in great measure due to the admirable work of both the city board of health and the Illinois State board.

PROLONGED HOT BATHS IN THE TREATMENT OF TETANUS.

MUCH as it is to be expected from the serum treatment of tetanus, it is not wise to give up the quest for other remedial measures for combating this terrible disease. Dr. Ribos Perdigo (*Revista de Medicina y Cirugía Prácticas*, February; *Giornale internazionale delle scienze mediche*, April) thinks that the chief value of the serum treatment will turn out to be as a prophylactic, and he has found prolonged hot baths efficient in the treatment of the actual disease. The temperature of the bath, he says, should be varied according to the state of the patient, but as a rule it should be about 97° F. The bath acts as a general sedative to the nervous system. Ordinarily each bath should last from two to four hours, sometimes longer, and the intervals between them should be as short as the state of the patient's strength will admit of. Along with this treatment all precautions should be taken to protect the patient against noise and other exciting influences.

THE BOHEMIAN TWINS AND THE TWO-HEARTED NEGRO.

IN the *Indian Medical Record* for April 12th we find an editorial paragraph entitled Which is the Most Wonderful Human Curiosity Now Living? The writer describes two young Bohemian women whose bodies are joined back to back, and goes on to say that until quite recently there was living in New Bedford, Massachusetts, a negro named King who had two separate hearts and two breastbones, but was "without the diaphragm, or muscular partition which separates the thorax, or

chest cavity, from the abdomen." King is further said to have "lived to upward of a hundred." From all this we deduce that King, if he ever existed, is now no more, and we wonder why our esteemed Indian contemporary treats him as a "curiosity now living." We suspect that what is said about King was taken from some newspaper, for surely the *Record* would not think it necessary to define the diaphragm and the thorax for its readers' benefit. Can any of our readers furnish trustworthy information concerning the negro in question?

THE DEGREE OF DEVELOPMENT OF A FETUS PAPYRACEUS AS SHOWN BY THE RÖNTGEN RAYS.

UNDER certain circumstances it may be important from the medico-legal point of view to ascertain the stage of development at which the fetus perished. According to M. Bouchacourt (*Obstétrique*, March 15th; *British Medical Journal*, April 29th), this can be accomplished by means of a Röntgen-ray examination, for the skeleton shows no sign of absorption even when the soft parts have almost disappeared. Some of the bones, however, are apt to be fractured, especially the ribs and the clavicles.

MUSCULAR ATROPHY OF THE SKIN.

At a recent meeting of the Moscow Venerologico-dermatological Society (*Monatshefte für praktische Dermatologie*, May 1st) Dr. Pospelow showed a patient affected with what Jadassohn termed anetoderma erythematosum. Pospelow proposed for the disease the name of purpura atrophicans, but, inasmuch as, on microscopical examination, he found the affection to be due to chronic inflammation of the walls of the blood-vessels, with absence of elastic tissue, it may be that his purpura atrophicans is the same thing as Mackenzie described, so long ago as in 1883, under the name of vascular purpura.

THE PER CAPITA CONSUMPTION OF ALCOHOL IN VARIOUS COUNTRIES.

In the *Journal of the American Medical Association* for May 13th there is a letter from Dr. T. D. Crothers giving an account of the recent international congress against the abuse of alcohol. It seems that a statistical table was presented showing that a larger quantity of spirits, including wine and beer, was consumed per capita in France than in any other country, and the smallest quantity in Canada. The table "was given as authentic," but it seems to us that the figures may be misleading, for, although a great deal of wine is drunk in France, the French are among the soberest peoples of the world. Much depends on what is meant by the word "consumed." Great quantities of crude spirit and inferior wine are sent to France to be "doctored" for exportation. It would be interesting to know if this is reckoned as "consumed" by the people of France.

THE PHYSICIAN IN GENERAL LITERATURE AGAIN.

THIS time it is a woman, Eugénie R. Elisen, M. D., said to be a Roumanian lady practising medicine in New York. Her little book, entitled *Satan's Hoof and the Two Witches*, is published in Boston, by the Banner of Light Publishing Company, which publishes "the oldest journal in the world devoted to the spiritual philosophy." A sad but simple story, which came in

itself, forms the skeleton on which the author displays the amazing productions of her fancy. As they relate largely to matters of science, there is some danger that ill-instructed readers may take them as a serious exposition of accepted doctrine, but this of course is not the author's intention. Dr. Elisen's style of writing is vivid, but it is marred by many a slip in English. If our fair colleague ventures again into the field of *belles-lettres*, we should advise her to have her manuscript revised by somebody who knows the English language thoroughly.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 20, 1899:

DISEASES.	Week ending May 13.		Week ending May 20.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	26	6	12	8
Scarlet fever.....	171	14	196	14
Cerebro-spinal meningitis.....	0	9	0	8
Measles.....	377	18	438	18
Diphtheria.....	175	26	219	25
Croup.....	12	6	13	10
Tuberculosis.....	199	161	170	141
Small-pox.....	1	0	1	0
Chicken-pox.....	37	0	32	0

The Annual Meeting of the American Medical Editors' Association will be held in Columbus, Ohio, on Monday, June 5, 1899, the day immediately preceding the opening of the annual meeting of the American Medical Association.

Dr. Thomas H. Hawkins, of Denver, is president, and Dr. Dillon Brown, of New York, secretary.

The association, in addition to the transaction of routine business to come before the body, will listen to a paper entitled *The Ends and Aims of Medical Journalism*, by Dr. J. D. Emmet, editor of the *American Gynecological and Obstetrical Journal*. In addition to this, the committee have proposed a brief collection upon the subject *The Editor and the Author—The Rights of Each as Regards Contributed Articles*. The committee has requested Dr. G. H. Simmons, editor of the *Journal of the American Medical Association*; Dr. J. Riddle Goffe, editor of the *Medical News*; Dr. G. M. Gould, editor of the *Philadelphia Medical Journal*; Dr. J. C. Culbertson, editor of the *Cincinnati Lancet-Clinic*; and Dr. Dunbar Roy, editor of the *Atlanta Journal-Record of Medicine* to lead in this discussion.

The Centralblatt für Laryngologie und verwandte Wissenschaften.—We are informed that Dr. Emil Mayer, of New York city, has been appointed the co-editor for America of this journal. The editor in chief is Sir Felix Semon, of London.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Obstetrics, on Tuesday evening, the 23d inst., the following papers were presented: Painful Menstruation, by Dr. C. E. Congdon; and Physicians, Surgeons, and Fees, by Dr. S. Y. Howell.

The St. Louis Medical Society.—At the last meeting, on Saturday evening, the 20th inst., Professor R. L. Gerner, of Chicago, read a paper entitled *Remarks*

on the Simian Voice and Speech; and Dr. M. Dwight Jennings and Dr. R. C. Blackner presented a stereoscopic demonstration of the structural changes of the kidneys in Bright's disease.

Marine-Hospital Service Health Reports.—The following cases of small-pox, cholera, and plague were reported to the supervising surgeon-general during the week ending May 20, 1899:

Small-pox—United States.

Mobile, Ala.	May 12.	2 cases.
Washington, D. C.	May 12-15.	3 "
Savannah, Ga.	May 9-16.	5 "
Chicago, Ill.	May 9.	2 "
Evansville, Ind.	May 6-13.	2 "
Emporia, Kan.	May 6-13.	2 "
Kansas City, Kan.	Apr. 29-May 6.	32 " 1 death.
Louisville, Ky.	May 4-11.	16 " 8 deaths.
New Orleans, La.	May 6-13.	9 "
Shreveport, La.	May 8-13.	4 "
Steeleton, near Baltimore, Md.	May 17.	4 "
St. Paul, Minn.	Apr. 29-May 6.	1 case.
St. Louis, Mo.	Jan. 21-May 12.	65 cases.
Las Cruces, New Mexico.	May 12.	19 "
Borough of Brooklyn, N. Y.	Apr. 29-May 6.	1 case.
Cleveland, Ohio.	May 6-13.	11 cases.
Allegheny, Pa.	May 6-13.	2 "
Johnstown, Pa.	May 6-13.	2 "
Philadelphia, Pa.	May 6-13.	1 case.
Providence, R. I.	May 10.	1 "
Barnwell County, S. C.	May 10.	3 cases.
Beaufort (not verified), S. C.	May 10.	3 "
Clarendon County, S. C.	May 6.	3 "
Edgefield County, S. C.	May 6.	5 "
Galveston, Texas.	Apr. 29-May 6.	7 "
Laredo, Texas.	Apr. 29-May 6.	2 "
Newport News, Va.	May 9-13.	5 "
Newport News, Va.	May 13-17.	6 "
Norfolk, Va.	May 11-18.	16 "
Portsmouth, Va.	May 11-18.	9 "
Milwaukee, Wis.	May 6-13.	2 "

Small-pox—Foreign.

Brussels, Belgium	Apr. 15-22.	1 death.
Cairo, Egypt.	Mar. 26-Apr. 22.	4 deaths.
London, England	Apr. 15-22.	3 cases.
Athens, Greece.	Apr. 22-29.	21 " 8 "
Bombay, India.	Apr. 4-18.	15 " 8 "
Calcutta, India.	Mar. 25-Apr. 8.	3 "
Bluefields, Nicaragua.	Apr. 22-29.	1 case.
Moscow, Russia.	Apr. 8-15.	8 cases.
Odessa, Russia.	Apr. 22-29.	5 " 1 death.
St. Petersburg, Russia.	Apr. 15-22.	18 " 3 deaths.
Constantinople, Turkey.	Apr. 17-24.	2 "
Constantinople, Turkey.	Apr. 24-May 1.	3 "

Cholera.

Bombay, India.	Apr. 4-18.	6 deaths.
Calcutta, India.	Mar. 25-Apr. 8.	43 "

Plague.

Bombay, India.	Apr. 4-18.	1,199 deaths.
Calcutta, India.	Mar. 25-Apr. 8.	266 "
Madras, India.	Mar. 25-31.	1 death.
Tamsui, Formosa, Japan.	Mar. 8-29.	394 deaths.

The Richmond Academy of Medicine and Surgery.—At the last regular meeting, on Tuesday evening, the 23d inst., a discussion on the diagnosis and treatment of mastoiditis was opened by Dr. J. P. Davidson.

The Chicago Society of Internal Medicine.—At the annual meeting, on Thursday evening, the 25th inst., a general discussion was opened on the prophylaxis and management of apoplexy.

Changes of Address.—Dr. E. Mather, from Jersey City to No. 22 Adams Avenue, W., Detroit; Dr. Otto H. Schultz, to No. 1109 Madison Avenue, New York.

The New German Hospital in Brooklyn was dedicated with appropriate ceremonies on Sunday, May 21st.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 13 to May 20, 1899:*

BARNHARDT, HENRY A., Acting Assistant Surgeon, will proceed to Camp Meade for duty.

CLEARY, PETER J. A., Lieutenant-Colonel and Deputy Surgeon-General, is detailed as a member of the army retiring board appointed to meet at Fort Sam Houston, Texas.

DEAN, ELMER A., First Lieutenant and Assistant Surgeon, is relieved at Fort Snelling, and will proceed to St. Paul as attending surgeon and examiner of recruits.

DE LOFFRE, AUGUSTUS A., Major and Surgeon, is directed to report to the army retiring board at Fort Sam Houston for duty.

DUNSHIE, JAMES F., Acting Assistant Surgeon, is relieved at Camp Meade and will proceed to Havana for assignment to duty.

DUTCHER, BASIL H., First Lieutenant and Assistant Surgeon, is detailed as a member of a board of officers appointed to meet at Fort Leavenworth for the examination of persons for appointment as second lieutenants.

GRANDY, LUTHER B., Acting Assistant Surgeon, will proceed to San Francisco for transportation by first transport to the Philippine Islands for assignment to duty.

GLENNAN, JAMES D., Captain and Assistant Surgeon, is relieved from the Department of Matanzas and Santa Clara and will rejoin his proper station, Fort Myer, Virginia.

HEIZMANN, CHARLES L., Major and Surgeon, is detailed as a member of the army retiring board appointed to meet at Fort Sam Houston, Texas.

KENNEDY, JAMES M., Captain and Assistant Surgeon, is relieved from muster out of troops at Augusta, Georgia, and will proceed to the Presidio of San Francisco and report to the commanding officer, Fourth Cavalry, for duty.

KILBOURNE, HENRY S., Major and Surgeon, is detailed as a member of a board of officers appointed to meet at the Army Building, New York, for the examination of officers for promotion.

M'Caw, WALTER D., Captain and Assistant Surgeon, in addition to duties as surgeon at Fort Porter, New York, is assigned as examiner of recruits in Buffalo.

MORRIS, JOHN E., Acting Assistant Surgeon, will proceed from New York to Indianapolis.

NETTELROTH, ALEXANDER, Acting Assistant Surgeon, will proceed to Louisville.

NORMAN, SEATON, Acting Assistant Surgeon, will proceed to Havana for assignment to duty.

PREYTON, CHARLES E., Acting Assistant Surgeon, is relieved at Camp Mackenzie, Augusta, Georgia, and will proceed to Richmond, Virginia.

PREVANCE, WILLIAM E., Captain and Assistant Surgeon, is relieved at Fort McPherson, Georgia, and will proceed to Washington and report in person to RAY, P. HENRY, Major, Eighth Infantry, to accompany him to Alaska as chief surgeon, District of Northern Alaska.

REAGLES, JAMES, Acting Assistant Surgeon, is relieved at Plattsburg Barracks, New York, and will proceed to Vancouver Barracks, Washington, for assignment to duty.

STEPHENSON, WILLIAM, Captain and Assistant Surgeon, is detailed as a member of a board of officers appointed to meet at the Army Building, New York, for the examination of officers for promotion.

STONE, OWEN W., Acting Assistant Surgeon, is relieved from the Department of Santiago and will proceed to Havana for assignment to duty.

STREET, BAEN, Acting Assistant Surgeon, is relieved at Camp Columbia, Havana, and will proceed to Washington and report to the surgeon-general.

TORNEY, GEORGE H., Major and Surgeon, is detailed as a member of a board of officers appointed to meet at Fort Leavenworth for the examination of persons for appointment as second lieutenants.

WILSON, ROY A., Acting Assistant Surgeon, will proceed to Camp Meade for duty.

ZAUNDER, ROBERT H., Acting Assistant Surgeon, will proceed to Camp Meade for duty.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending May 11, 1899:*

MURRAY, R. D., Surgeon. Granted leave of absence for fifteen days from June 4, 1899.

PECKHAM, C. T., Surgeon. When relieved from duty at New Orleans, Louisiana, by Passed Assistant Surgeon J. A. NYDEGGER, to rejoin station at Pittsburgh, Pennsylvania. To proceed to Neville Island, Pennsylvania, for special temporary duty.

VAUGHAN, G. T., Passed Assistant Surgeon. Detailed by the Secretary of the Treasury as delegate to represent the Treasury Department at the meeting of the International Tuberculosis Congress at Berlin, Germany, May 24th to 27th, inclusive.

NYDEGGER, J. A., Passed Assistant Surgeon. To rejoin station at New Orleans, Louisiana.

STEWART, W. J. S., Passed Assistant Surgeon. To proceed to Nantucket, Massachusetts, for special temporary duty. May 10, 1899.

MCMULLEN, JOHN, Assistant Surgeon. Upon being relieved from duty as Sanitary Inspector on United States transport *Buford*, to report to the medical officer of the service at the United States Immigration Depot, New York, for temporary duty.

VON ECKHART, R. H., Assistant Surgeon. Detailed as Inspector of Quarantines.

HEISEL, V. G., Assistant Surgeon. Detailed by direction of the President for duty in the office of the United States Consul at Naples, Italy. Upon being relieved from duty at the Immigration Depot, New York, to report at Washington, D. C., for instructions preliminary to departure for Naples, for duty.

HONDY, W. C., Assistant Surgeon. Relieved from duty at the Reedy Island Quarantine Station and directed to proceed to Stapleton, Staten Island, New York, and report to medical officer in command for duty and assignment to quarters.

CORBIT, G. M., Assistant Surgeon. Granted leave of absence for seven days.

Board Convened.

Board convened to meet at Detroit, Michigan, on May 20, 1899, for the physical examination of Surgeon

JOHN GODFREY, M. H. S. Detail for the board: Surgeon H. W. SAWTELLE, chairman; Passed Assistant Surgeon G. M. MAGRUDER, recorder.

Society Meetings for the Coming Week:

TUESDAY, May 30th: American Dermatological Association (first day—Philadelphia); Rome, New York, Medical Society.

WEDNESDAY, May 31st: American Orthopaedic Association (first day—New York); American Surgical Association (first day—Chicago); International Association of Railway Surgeons (first day—Richmond); American Dermatological Association (second day); Auburn, New York, City Medical Association; Berkshire, Massachusetts, District Medical Society (Pittsfield).

THURSDAY, June 1st: Indiana State Medical Society (first day—Indianapolis); Michigan State Medical Society (first day—Kalamazoo); American Orthopaedic Association (second day); American Surgical Association (second day); International Association of Railway Surgeons (second day); American Dermatological Association (third day); New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, New York; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, of St. Louis.

FRIDAY, June 2d: Indiana State Medical Society (second day); Michigan State Medical Society (second day); American Orthopaedic Association (third day); American Surgical Association (third day); International Association of Railway Surgeons (third day); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, June 3d: American Academy of Medicine (first day—Columbus, Ohio); Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Births, Marriages, and Deaths.

Married.

KELLERS—BRODIE.—In Charleston, South Carolina, on Thursday, April 27th, Dr. Henry C. Kellers and Miss Edyth M. Brodie.

O'NEIL—MEYERS.—In Richmond, Virginia, on Wednesday, May 17th, Dr. Richard E. O'Neil, of Boston, and Miss Adela Pegram Meyers.

WHEATON—WILT.—In Chicago, on Wednesday, May 17th, Dr. Clarence Lloyd Wheaton and Miss Caroline Georgiana Wilt.

Died.

CANDIDUS.—In Brooklyn, on Tuesday, May 16th, Bertha Candidus, wife of Dr. P. C. Candidus.

FILSON.—In Burlington, N. H., on Saturday, May 20th, Dr. J. B. Filson.

GALBREATH.—In Pottsville, Pennsylvania, on Tuesday, May 20th, Dr. Thomas Galbreath.

MCENROE.—In New York, on Wednesday, May 17th, Dr. William Hale McEnroe, aged forty-four years.

NIVISON.—In Roseville, New Jersey, on Friday, May 19th, Dr. Mark Nivison, of New York, in the sixty-first year of his age.

STICKLER.—In New York, on Thursday, May 18th, Dr. Joseph William Stickler, of Orange, New Jersey, aged forty-five years.

Letters to the Editor.

POISONOUS DOSES OF GELSEMIUM IN THE TREATMENT OF INFLUENZA.

OXFORD JUNCTION, IOWA, May 11, 1899.

To the Editor of the *New York Medical Journal*:

SIR: I see a mention in the *Journal* for May 6th of gelsemium in grippé. I know nothing of Dr. Barry's original article, but, as the editor seemed a little skeptical, I should like a few words with you. During the winters of 1889-'90 I used tincture of gelsemium in grippé with what I thought unusual success. But I dreamed not of the virtues of the drug I was using. About February 15, 1891, J. M. came to my stable just as I was leaving for a three or four hours' drive. He had been taken during the night with an unusually severe attack of grippé, all symptoms being exaggerated. Being in a hurry to start, I told him to go to my house and tell my wife to give him two teaspoonfuls of tincture of gelsemium, and I told him to take it in half-spoonful doses every three hours. Knowing his tendency to double all doses, I carefully cautioned him not to do so in this case, for I was then giving him a full dose. Mrs. B. again cautioned him and told him he was getting a very large dose as it was directed. I returned home a little after noon and went in to see the patient. I found him lying across the bed in a deep sleep, breathing deeply and heavily. His pulse was weak but regular. I asked about his medicine, and found that he had taken half a spoonful at 8 A. M., a spoonful at 8.30 A. M., and the last half spoonful at 9 A. M. I told his wife that he would probably lie there all the afternoon and advised her to let him rest.

At 9 P. M. I called again, and he had not changed his position. We pulled him around on the bed, took off his shoes, and covered him up, and I left him for the night. The next morning he was up and at my house early with not a symptom of the grippé remaining, cured, absolutely cured, of a severe attack of grippé in twenty-four hours. He then described his feelings after taking the last dose, and told how badly he wanted me with him, and said: "Why, doctor, I could not move nor speak. I thought I was a goner."

In a few days our hotel landlady was taken in the same way as Mr. J. M. had been. She was taken about noon, and I saw her about 9 P. M. She knew of the above-mentioned case and said: "Now, doc, get me out of this quick, for I have no time to be sick." I asked her if she wanted a J. M. dose, and she said: "I will take anything, just so you don't kill me." I explained all the effect and symptoms of an overdose of the medicine and prescribed thirty drops of tincture of gelsemium every hour till she was well under the influence

of the same. She took three or four doses, and the next day she was well.

The third patient was a young man who had ridden several miles to attend the funeral of his grandmother. He was taken during the night, and I was called the next morning. He expressed his desire to be "out of this" soon, for his business called him home. I told him of the above-mentioned cases and asked him if he would take the medicine in poisonous doses. He replied that he would. So I explained the effect, prescribed as in the second case, and left him. The next day he was in town, three miles from his grandparent's, and said: "I am as well as I ever was."

From these three cases I concluded that gelsemium was a specific for *la grippé*, and after six years' experience with it I am more certain than before. After this treatment there are no sequelæ, and, if it is begun in time, no complications. To relieve the pain, aches, etc., I usually prescribe some anodyne tablets, and know of none better than antikamnia. L. K. BOBO, M. D.

* * Our correspondent has certainly been fortunate in his use of poisonous doses of gelsemium. It is a drug that we are taught to use with great caution even in ordinary doses, and it should be borne in mind that death has resulted from taking thirty-five drops of a tincture of the bark (the rhizome and rootlets are the official parts of the plant), also that somnolence and inability to move or speak are not the only symptoms of gelsemium poisoning. Possibly Dr. Bobo used a tincture that was of less than the official strength. We feel it our duty to caution the reader against the use of overdoses of poisonous drugs, no matter how much good they may have accomplished in the hands of others.

THE PERIOD OF INCUBATION OF MEASLES.

359 MASSACHUSETTS AVENUE, BOSTON, May 23, 1899.

To the Editor of the *New York Medical Journal*:

SIR: A word more concerning the period of incubation of measles is rendered necessary by the probably hasty reading of my first letter by Dr. George M. McCombs. He thinks the infection was spread by the "little sister" for whose books the boy came. My words are "his books." The little sister was too young to be in school. Some more explanation concerning the boy may make clear the reason of his carrying so much of the contagion about with him while a physician does not do so. The boy was one of those degenerates known in the South as "poo' white trash." Some few of this class of being are found in the lowest classes of the public schools all over the country. The whole family lived in a two-room cabin on the outskirts of the town. The boy was dirty and unkempt, which he excused by saying that he had not come to stay in school that day. He had on an old topcoat into which he had been pinned before he left his home. He had been absent a week from school, and had very likely lived day and night in the suit he had on during that time, judging from the odor which exhaled when he removed his topcoat, which I purposely required him to do before he took his seat. This topcoat retained in the fibres of his house clothing all the contagion with which he had left home, none, or at least very little, being lost by the way. Had this boy been the inmate of a cleanly home, where he would have received a bath and been dressed in a fresh suit before leaving for the school-room, I should not have considered the experiment worthy of a trial.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XX.

RECOVERY OF COMPENSATION.

(Continued from page 718.)

Repeal of Disqualifying Act, Effect on Services Previously Rendered.—But what effect, if any, does the repeal of a disqualifying act have upon the physician's right to recover for services which were unlawfully rendered before such repeal? Here again we find some conflict of authority, the supreme court of Massachusetts being of the opinion that the disqualifying act was not designed to prevent the debt from accruing, but was intended to deprive the physician unlawfully practising from the means of enforcing the payment of such debt, and therefore when the disqualifying act was repealed the obligation stood complete, and the means of enforcing it by legal proceedings were immediately available.*

The courts of all of the other States which have passed upon the question have, however, repudiated this doctrine, they holding, with better reason, it seems, that such contracts are void in their inception, and that the repeal of the disqualifying act can therefore raise no obligation on the part of the patient and create no right to recover on behalf of the physician.† It has been heretofore observed that the repeal of an act making it a penal or criminal offense to practise medicine without legal qualifications takes from the court the power of enforcing the penalties incurred under such repealed law; the distinction made between the criminal and civil rights in such a case may be regarded as another evidence of the policy of our law to throw about the accused every reasonable protection of law.

Steps for Consideration in Enforcing a Claim.—If, on the other hand, the physician has perfected his legal status, as nearly all practising physicians and surgeons have done, it then becomes pertinent to consider the various steps in the process of enforcing payment by legal measures.

Action will lie in this Country for Physicians' Fees.—It has been observed that in England, until the medical acts passed during the present reign, the physician was not entitled as a matter of legal right to recover compensation for his services, the law considering them of so exalted and honorable a character that it would not encourage the suspicion that they had been rendered from so unworthy a motive as that of a mercenary. Moreover, Lord Kenyon, in a case in which he refused to enforce the payment of a fee, expressed his doubt whether the physicians would not disclaim a right which would place them in society on a footing with common men.‡ However justified the opinion of Lord Kenyon may have been at the time and place of its expression, it was not approved by the wisdom of the succeeding century in his own country, nor has it ever been considered suitable to the conditions of this

country. Justice Stevens, of the supreme court of Indiana, in considering the application of the English doctrine by our courts, said with perspicuity and unanswerable logic: "It is true that we have adopted the common law of England, but it is a qualified adoption. We have only adopted so much of it as is of a general nature and not local to that kingdom, and not inconsistent with our own laws. We have not adopted any part of it that is peculiar to that country, or that is contrary to, or inconsistent with, the spirit and practice of our own institutions. It is at least doubtful whether the principle here contended for was any part of the common law at the time the States of this Union dissolved their allegiance to that kingdom; but if it were, it is clearly a principle which is local to that country, and is inconsistent with the spirit and genius of all our institutions and the practice of our courts. Our institutions and laws are all based on the great and broad principles of liberty and equality, and know nothing about nobles and ignobles, honorables and common men. There is but one class known: all stand upon the same footing, and bow with equal submission to our common master—that is, the law of the land. We have no privileged orders known to the law, either as to suing or being sued."*

The physician entering court upon the common plane of all litigants must come prepared with proper and sufficient evidence to show those facts upon which he bases his right to recover.

Limitations of Actions.—Perhaps the first question to consider at this stage is the age of the claim: is the account barred by the statute of limitations? If so, would the patient be willing to plead such a defense to defeat recovery?

The statutory period of limitation upon the different classes of debts and obligations varies so greatly in the several States that no general statement of the law can be made; but recourse must be had in each case to the statutes of the particular State to determine whether or not the claim is within the period of limitation.

If the account consists of a single item, it is a simple matter to determine whether it is within or beyond the prescribed period; but perhaps the account consists of a series of items extending over a period of several years, the earlier of which items are beyond the limit. Is the right to recover such items barred? Nearly every State recognizes the doctrine of mutual accounts, which is founded upon the presumption of a mutual understanding that the parties to the account will continue each to credit the other until either desires to terminate the dealing, when the balance will be ascertained and will be considered as accruing at the date of the last item of the account. Neither Louisiana † nor Texas, however, accept this doctrine, but in case of a continuous account consider the statute of limitations as running against each item from the date of its entry. New Hampshire also denies the rule, excepting as between merchant and merchant.‡

Whether the ordinary account of a physician—that is, an account consisting of charges for professional services on the one hand, and of credit for the payment of fees by the particular patient on the other hand—will constitute a mutual account is a question upon which the courts of the different States are divided

* Hewitt vs. Wilcox, 1 Met. 124.

† Pickett vs. Alexander, N. C., 3 E. R. A., 44, 8 S. F. Rep. 467.

Bailey vs. Mogg, 1 Denis, 60 (N. Y.); Nicholson vs. Boulton, 1 Omo, 305; Warren vs. Saxby, 12 Vt. 146; Quarles vs. Evans, 7 Tex. Ann. 544.

‡ Chorley vs. Bolcut, 1 T. R., 317.

* Judah vs. McNamara, 10 Ark. 461 (1846).

† Arismeneux vs. Lefebvre, 6 Robt. 450.

‡ Blair vs. Price, 6 N. H., 15.

The doctrine more commonly accepted is that an account to be mutual must be the result of a mutual exchange of commodities or services, the mere payment of money on one side not being considered sufficient to make the account mutual so as to prevent the bar of recovery. This is the law in California, Georgia, Indiana, Maine, Maryland, New York, and Pennsylvania.

On the other hand, the supreme court of Michigan holds that a payment made upon an account will render the whole account open and mutual, so as to take the earlier charges out of the operation of the statute of limitations.*

This question seems, unfortunately, to be one upon which there is considerable conflict and uncertainty, the court of the same State even contradicting itself in the course of a few years; † therefore the only safe method one can adopt in carrying long accounts of the sort is to have an occasional settlement or accounting in which the balance is either liquidated by cash or note, or is carried forward as a new account, or for the new period of time; in such a case the statute of limitations will run anew from the date of such settlement or accounting. ‡ If the settlement is effected by carrying the balance forward, it is essential that the debtor should have the account before him, and should agree either expressly or impliedly to the correctness of the new balance.

In case the account is found to be barred, it then becomes necessary to determine whether the patient would avail himself of a defense of this character, for suit may be commenced upon a claim against which the statutory period has run, either in whole or in part, and unless the defendant specially pleads the statute as a defense, judgment may nevertheless be entered in the plaintiff's favor for the full amount of the claim.

Particularity of Items of Account.—As to the particularity with which the account must set forth the items of the bill upon which suit is begun, it may be stated generally that this depends upon the nature of the account. If the account is one upon which there has been no settlement or liquidation of the character referred to in the preceding paragraph, each item should be charged separately and under the date upon which the particular service was rendered, with a specific sum charged for each visit or item entered upon the account. There are cases holding that such particularity is not necessary, § but there is not sufficient authority to justify one in ever keeping or preparing an account with less particularity.

In an early South Carolina case the bill sued upon contained an item of "thirteen dollars for medicine and attendance on one of the general's daughters, in curing the whooping-cough." A new trial was asked for on the ground that the physician ought to have given a specific bill of the medicine and attendance. The court, through Justice Smith, said: "I did think otherwise on hearing this case; but on mature consideration I think the charges were too general, and am, therefore, for granting a new trial." ¶ The question of whether or not the account is sufficiently specific must be decided by the court according to the prevailing usage in similar cases. §

§ *Van Bibber vs. Merritt's Exr.*, 12 Weekly, N. C., 272.

¶ *Hughes vs. Hampton*, 2 Tread. Const. (S. C.), 745.

§ *Schmidt vs. Quin*, 1 Mill Const., 418 (S. C.).

Regarding the character of the visits or services performed, and the kind and amount of the medicines charged, it does not seem necessary that the bill should be descriptive. In an early New Hampshire case in which the items were specified as "to visit" and "to medicine," the court said: "Had this been shown to be different from the usage of medical men, it might be proper to inquire into the character of the disease and the circumstances under which the services were performed; but the charge stands well enough until something is shown to the contrary. There is nothing upon the face of the charges to create any suspicion of their correctness; and we can not, without evidence, make any presumption against them. Or, if there had been a general charge for visits and medicines throughout the year, and a gross sum affixed thereto, for compensation to the physician and for medicines furnished, there might be some reason for inquiring into it. But here is a specific sum charged for each visit; and it was competent for the defendant to show that the services were not rendered and that the charges were unreasonable, if such had been the facts." *

From the preceding quotation the reader will realize the necessity in case of an unusual charge of specifying the character of the services rendered. If, for instance, a minor operation were performed, or if unusual services of any character were rendered while making a visit, and yet the item appeared upon the bill as a "visit," with the proper amount charged for the real services performed, the difference between the sum charged and the amount ordinarily charged for a mere visit would be so great as to create a suspicion as to the correctness of the bill.

Is Proof of License Necessary?—Perhaps the first question to decide upon commencing suit is whether it is incumbent upon the physician, or plaintiff, to prove that he has fully complied with the law of his State and was duly qualified to practise medicine at the time the services in question were rendered; or whether this will be presumed until contradicted or disproved by the defendant. Upon this question there is again a difference of opinion in the courts of the different States.

Probably the rule best founded on reason and justice is that in civil suits between physician and patient the physician's right to practise medicine will be presumed until disproved, or at least disputed; while in cases of a criminal prosecution against one for practising medicine unlawfully, he must prove himself to have complied with the law. This rule is very clearly laid down by Justice McAllester, of the Illinois appellate court, who says: "After a thorough examination of the authorities, and a full consideration, we are of the opinion that the rule with its proper distinctions may be thus stated: Where the question of license or qualification of a physician arises collaterally in a civil action between party and party, or between the doctor and the one who employed him, then the license or due qualification under the statute to practise will be presumed; but in case of a prosecution on behalf of the public the rule is otherwise, and in such cases license or due qualification under the statute is not presumed, and it rests with the defendant to prove it." †

A sound reason for this rule is that when an act is required by positive law to be done, the omission of which would be a misdemeanor, the law presumes that

* *Bessett vs. Spafford*, 11 N. H., 167.

† *Williams vs. People*, 20 Ill. App., 93.

it has been done, and therefore the party relying on the omission must make some proof of it.*

There is considerable doubt cast upon the full application of this rule in Illinois by a more recent opinion of the supreme court of that State. The court, after referring to the decision sustaining the above rule, expresses a desire not to commit itself in the case they were then considering, which was one between third parties in which the physician's qualifications arose only collaterally, but they said: "If he (the physician) were himself suing to recover for his professional services, he would doubtless be required to show affirmatively his compliance with the law, but between third parties the fact that he is and has for a long time been practising as a physician and surgeon is sufficient to show, *prima facie*, that he is lawfully authorized so to do."†

At an early date the supreme court of New York decided squarely upon the point, holding that in a suit by the physician for his fees a license would be presumed until the contrary was shown.‡

The supreme court of Louisiana, also at an early date, held that where one acknowledged a physician as such by employing him to render professional services such acknowledgment was *prima facie* evidence that he was duly qualified,§ but that when the defendant in the suit propounded interrogatories to the physician regarding his license, and he failed to answer them, such failure would be taken as confessing that he had no license to practise.||

On the other hand, the rule that a physician must, upon suing, prove that he has secured a license in conformity with the law, was acknowledged as the law in Delaware in 1849.¶

The supreme court of Georgia declared such rule to be the law in that State as early as 1850. In 1855 the supreme court of Alabama said: "The effect of these statutes, taken together, was to prohibit all persons from practising as physicians, unless they were licensed by a medical board in their State, or their names were enrolled according to the provisions of the statute, or unless they practised on the botanic system alone; and the necessary result of this prohibition would be to prevent a recovery in all actions founded on contracts for medical services, unless it was proved that the persons rendering such services were not within the prohibition."‡

The same rule is held to be the law in New Jersey: and Massachusetts.‡ The supreme court of Indiana, in a recent decision, after reviewing all of the principal cases on both sides of the question, expresses itself as believing that good reason exists in civil suits for the rule of presuming the physician qualified until the qualification is disputed or disproved, but the court adds: "The statutes under which these several rulings have been made, while similar to our own, none of them, so far as we know, provide, as does ours, that no cause of action shall lie in favor of any person for ser-

ices as physician who has not, prior to the rendition of such services, procured a license to practise." The court then argues that this clause in the statute has the effect of compelling the physician to prove that he has complied with the requirements of the law before recovering in a suit brought to collect the value of professional services.*

The statutes of some States contain the reasonable provision that no evidence of authority to practise medicine will be required as a prerequisite to a recovery for professional services unless notice is given by the defendant that he shall require proof upon that point. The court of appeals of South Carolina held in an early case that the physician's right to practise would be presumed unless the defendant gave him reasonable notice that proof upon that point would be required.‡

Regarding those States in which the question has not been decided, it is pertinent to say that no better advice can be given than: Assume that no presumption of law will be indulged in favor of the physician's right to practise, and have your case prepared accordingly.

In case of suit brought in one State for services rendered in another, no proof is necessary of the right of the physician to practise in the State in which the services were rendered, for the courts of the State in which suit is brought will not presume that the practice of medicine was restricted in that State.‡

Proof of Authority to Practise.—The character of proof required to show that one is qualified to practise medicine and surgery depends almost entirely upon the statutes of the particular State, and the preparation of this proof can be entrusted only to those skilled in the law; therefore it will be idle to give more than a very cursory review of the law upon this point. Probably the fundamental rule of evidence in making this proof is the simple one that *the best evidence of which the case, in its nature, is susceptible will be required.* This rule means that if a right is to be proved which has its origin or foundation in a diploma or license, then the right can be proved only by producing and proving the original diploma or license. Should, for instance, one living in a State requiring as a qualification to practise medicine that he shall have graduated from a regularly incorporated medical college, desire to prove that he has complied with this law, he must not only produce his original diploma, but he must show the incorporation of the college. And if the college does not owe its corporate existence to a special act of the legislature of that particular State, he must produce the act of incorporation; he must also show the existence of the college at the time the diploma purports to have been issued.*

Should the law not, however, provide that the degree shall have been issued by an incorporated body, then a production of the corporate records is not necessary.†

The courts at an early date required strict proof of all of these facts, never admitting a diploma as proof *per se* of its genuineness, but requiring that the genuineness of the parchment should be proved *abundant*.‡ The rigor of the law has, however, been somewhat ameliorated by statutes which frequently provide that when the physician has presented his diploma to the State

board of health or State board of medical examiners, and verified its genuineness, the board shall issue a certificate to that effect, and that such certificate and diploma shall be proof of the holder's right to practise medicine. In case of provisions of this sort the certificate serves to prove and identify the diploma. The statutes sometimes make the license issued by the designated board competent evidence without proof of the signature. Under such a statute it is incumbent upon the physician to simply offer the license in evidence as full proof of his rights.*

Pith of Current Literature.

Delusions and Insanity.—The *Occidental Medical Times* for January quotes the following from the *St. Louis Medical and Surgical Journal* of unspecified date: The supreme court of Tennessee has rendered an important decision in a case of murder in which a plea of insanity was set up. The court held that "in criminal cases the correct issue is not that of sanity, but of responsibility. The delusions of a sane man do not make him irresponsible. The question is in such cases, Is the delusion set up as a defense the delusion of an insane person? Many men of strong minds," continued the court, "have delusions. Remarkable instances are given in the works on medical jurisprudence of delusions in men of prominence in all the walks of life. Lord Kenyon had an unreasoning fear of poverty, and so had Lord Stowell, although he was a man of immense fortune, his home being absolutely destitute of the necessities and comforts of life. Lord Erskine would never sit at a table or remain in a company as one of thirteen persons. Lord Eldon, after he had made up his mind and expressed his opinion lucidly and conclusively, was at all times a prey to grave doubts of his correctness. Lord Brougham, upon more than one occasion, was placed in seclusion, his mind being clearly off balance. Judge Breckenridge, of Pennsylvania, is reported to have on a hot day, while holding court at Sunbury, gradually taken off his clothes until he sat naked on the bench. Judge Baldwin, of the United States supreme court, was a hypochondriac. A distinguished New England judge imagined that a dropsical affection, under which he labored, was a sort of pregnancy. And yet none of these men were insane, because they had reason and sanity enough to conquer and overcome these delusions. A familiar illustration is that of the Mormon elders, who claimed that they had a direct revelation from heaven permitting them to practise and teach polygamy. The world generally regards this as a rank heresy, and the claim to be the evidence of an unreasonable delusion. It has, however, been held that they can not defend on the ground of such delusion, inasmuch as otherwise they are sane, shrewd, active, successful, and unusually practical men in their business and social relations, and they have been held responsible for such delusions."

Acute Rhinitis and General Infection.—At the Liverpool Medical Institution Dr. Pernewan (*British Medical Journal*, May 13th) related a case of acute rhinitis

which had caused general infection of the system, and in which treatment of the nasal condition caused rapid subsidence of the fever. Dr. Carter said that in all cases of apparently inexplicable fever the nasal cavities should be carefully examined. He illustrated this general statement by brief reports of several cases, in one of which recurring attacks of what was believed by the patient to be malarial fever were prevented by thorough antisepticism of the nostrils, though the attacks had been going on for years. In another case a married woman, aged twenty-three years, admitted to hospital on March 12, 1896, with a temperature of 104.2° F., and a history of illness of some months' duration, the fever at once began to decline after the use of nasal antiseptics and in a few days completely subsided, and although she was detained in hospital for three weeks no recurrence took place. He had published reports of eight or ten cases of most serious and prolonged general illness of a very mysterious character that had come under his notice during the last twelve years, all of which were completely cured by thorough antiseptic treatment of the internal nares. Two of the patients were judged to be *in extremis* when the treatment was commenced, and a third had been continuously ill for eighteen months.

Some Points in Appendicular Inflammation.—Mr. H. Betham Edwards (*Lancet*, May 6th) deduces from a paper on Some Complicated Cases of Appendicitis the following points: 1. In a small proportion of cases of appendicitis with abscess there is intraperitoneal extension to the liver region. 2. In relation with the liver pus may be only below it or also above it, "subdiaphragmatic." 3. Clinically there is considerable difficulty in determining, when the apparent upper border of the liver is raised, how much of this is due to simple displacement upward by a fluid collection, or to a subdiaphragmatic abscess, or to an associated lesion at the lung bases.

Osler on Chronic Splenic Enlargement with Recurring Gastro-intestinal Hemorrhages.—Dr. William Osler (*Edinburgh Medical Journal*, May) says that, excluding the enlarged spleen of leucæmia, chronic malaria, cirrhosis of the liver, heart disease, and rickets, the cases of so-called primitive enlargement of the organ fall into two groups.

First, a series in which the spleen is enlarged without causing any symptoms other than those due to mechanical pressure. In the past few years the author has seen four patients, all women, apparently in perfect health, who complained only of a feeling of pressure in the abdomen, in all of whom the spleen was much enlarged. In two cases in which the organ was freely movable and caused a great deal of discomfort, his colleague Halsted opened the abdomen and successfully packed the spleen in position with gauze, an operation much less serious than splenectomy and very efficacious. Both these patients have been seen more than two years subsequent to the operation, and have remained quite well. In a third case a girl was sent into the gynecological department, supposed to have an ovarian tumor. She was robust and strong, with good color, and had been hard at work. She subsequently had a twist of the ligaments and splenicus of the spleen, with enormous enlargement, adhesion to the abdominal wall, redness, and inflammation. The organ was freely incised by Halsted, and an enormous quantity of necrotic spleen tissue removed; the patient made a good recovery. This condition is, Dr. Osler thinks, more common than is

* White vs. Martin, 38 Ala., 447.

suspected. The spleen is, as a rule, only moderately enlarged. In some cases there has been a history of past malaria, but in a majority the condition is one of, so far as can be seen, primary enlargement. It must not be forgotten, he says, that only a blood examination can determine whether or not such patients have leucæmia, since in this disease, as is well known, an individual may look well, and have indeed nearly a normal number of red blood-corpuscles.

Secondly, cases of enlargement of the spleen with anæmia, Griesinger's anæmia splenica, the splenic pseudo-leucæmia of H. C. Wood, or, as it is sometimes termed, the splenic variety of Hodgkin's disease. Dr. Osler prefers the name splenic anæmia, introduced by Griesinger. The term, he says, should be restricted to the class of cases in which a progressive anæmia develops in connection with a primitive splenomegaly. The relation of the enlarged spleen to the anæmia is still in doubt, whether the perverted state of the blood is due to splenic inadequacy (which does not seem at all probable, since removal of the spleen has cured some cases), or whether both the enlarged spleen and the anæmia are due to some chronic toxæmia. In the author's experience the cases have not been uncommon. He has seen four cases during the present year, one with Dr. Graham, of Toronto, two reported in his paper, and a fourth, which is at present under observation.

Among peculiarities which have been illustrated by his cases, he mentions the following: The remarkably chronic course, extending from three to twelve years; the chlorotic features of the blood, the hæmoglobin value often not more than fifty per cent.; the peculiar bronzing of the skin, not a jaundice, which was not present in any of his cases; and, lastly, hæmorrhages, which may be toxic, as in leucæmia, and widespread, or mechanical, resulting directly from the condition of the enlarged spleen.

It is to this latter point he wishes to call particular attention, a condition in which for many years hæmorrhages occur from the stomach and bowels. The bleedings are profuse, and in the cases he records have occurred during a period of from nine to twelve years, while in the intervals the patients have regained their flesh and strength and have been able to carry on their occupations.

Hæmorrhage in chronic enlargement of the spleen has, he says, long been recognized by Latour, Franck, Morgagni, and others. The best section on the subject in any modern work is that given in Watson's *Practice*, in which he gives the following explanation: "It seems to me highly probable that one at least of the offices of the spleen is to provide a receptacle or reservoir for this blood, when its free passage through the portal vessels is temporarily obstructed. It then becomes a sort of safety valve (if such an illustration be allowable), which obviates the danger that might otherwise arise to non-vital parts from any great or sudden disturbance of the venous circulation. The stress of the congestion is continually felt in the subcutaneous capillary system, and the hæmorrhage which is apt in such cases to occur from the loaded membrane receives a simple solution, upon principles almost purely mechanical."

When in Montreal, Dr. Osler's attention was called to the subject by the occurrence of several interesting cases, and in 1882 he published a short paper, and reported four cases. Of these, two occurred in leucæmia, and were of special interest, inasmuch as the hæmorrhage was the symptom to call attention to the condi-

tion: in one case, indeed, the diagnosis of leucæmia was only made post mortem. Of the other two cases, one was an instance of ordinary splenic anæmia, in which, in association with a greatly enlarged spleen, the patient had in January and July, 1879, severe hæmorrhages from the stomach, and later in the same year died in a third attack. The fourth case possibly comes in the group to which he particularly wishes to call attention. The patient, a child aged eleven years, had a greatly enlarged spleen without leucæmia. There had been swelling of the abdomen for two or three years, and at her ninth year, two years before he saw her, she had a severe attack of hæmorrhage from the stomach. There was an indefinite history of a previous attack, four years before her visit to him. A month before Dr. Osler saw her she had a very severe attack, in which she vomited in a couple of days nearly three quarts of blood. In the intervals she had thrived well, though she always looked a little pale. The red blood-corpuscles were 2,250,000, white corpuscles, 6,696 to the cubic millimetre.

In 1890 a case of hæmorrhage from the stomach, in association with splenic anæmia, was admitted to the Johns Hopkins Hospital. A young man, aged twenty years, had lived in a malarial district, but had never had chills and fever. In April of 1889, after feeling badly for a month or so, he vomited blood, and afterward passed dark blood in the stools. In May, his physician for the first time noticed an enlargement of the spleen. In June he applied at the out-patient department of the hospital, when he had an extreme degree of anæmia and a greatly enlarged spleen. On admission, January 11, 1890, he had a great deal of pigmentation of the skin, and the spleen was very large, reaching nearly to the navel. The red blood-corpuscles were slightly over 2,000,000 to the cubic millimetre, and the leucocytes a little over 12,000 to the cubic millimetre. He gained rapidly in weight, had no further hæmorrhage, was discharged on March 24th, and has not since been heard from.

Dr. Osler next reports three cases characterized by a remarkably protracted course of from nine to twelve years, during which time hæmorrhages, at times of great severity, took place from the stomach and bowels.

Dr. Osler next records three cases in full detail, and concludes by remarking that the special feature of hæmorrhage he regards as entirely due to mechanical causes. In none of his cases have there been associated cutaneous or retinal hæmorrhages, such as are often seen in leucæmia. He does not think anything can be added to Watson's explanation. In support of this, he refers to the anatomical fact that a very large portion of the blood from the stomach is discharged into the splenic vein. Based on the measurements of the areas of all the main branches of the splenic artery, it has been estimated that of its blood sixty per cent. passes to the spleen, and forty per cent. to the stomach (Mall, Kansas). The veins of the vasa brevia passing from the fundus of the stomach are very large, and though he can find no estimate of the relation which they bear to the other veins of the organ, yet they certainly must drain a very large section of the organ.

The diagnosis of condition associated with enlargement of the spleen is important, but is often complicated, owing to the number of diseases which give evidence of the atrophy of the various tissues of the body in relation to one another. We must not confuse a primitive splenomegaly with a primitive leucæmia, and a splenic count. The cases of chronic enlargement of the spleen, extend-

ing over many years, present, as a rule, an anæmia of a chlorotic type, with low hæmoglobin and low leucocyte count. The more pronounced does the corpuscular anæmia become, the more striking are the changes in the red blood-corpuscles, and in advanced cases the blood may be like that of a pernicious anæmia. The most confusing and puzzling condition, however, is that in which, with enlargement of the spleen, the condition of leucæmia may be presented during one month, and in the following month that of a simple splenic anæmia. A patient at present under his observation had in May and July an extreme degree of leucæmia, while at the end of September, with a moderately enlarged spleen, he had a simple anæmia with a slight increase in the polymuclear leucocytes.

And lastly come the question of the diagnosis from Banti's disease, primitive splenomegaly, with an associated terminal cirrhosis of the liver and jaundice. Osler has never met with an instance; but two of the cases he has reported illustrate how careful one must be in the diagnosis *intra vitam*. All three cases reported in his paper have the chronic character and the severe hæmatemesis, features upon which Banti lays a good deal of stress. There were no changes whatever in the liver in Case I microscopically, and macroscopically in Case II the liver looked perfectly normal. It is to be noted also in the clinical report on both these cases that the area of liver dullness seemed considerably reduced, and in Case I the author was rather inclined to regard the hæmorrhage as of hepatic origin.

Moreover, a certain number of cases of splenic anæmia, he says, present ascites quite early in their course, and an instance of this kind has been recently under his observation in a physician from Illinois, who had an enlarged spleen for at least four years, with ascites in May, 1895. Death occurred in the early part of this year, with ascites. The autopsy showed only an enormously enlarged spleen without cirrhosis of the liver.

Oxycamphor in Dyspnœa.—Dr. Alfred Ehrlich (*Centralblatt für die gesammte Therapie*, 1899, Heft i, S. 1; *American Journal of the Medical Sciences*, April) presents oxycamphor as a remedy for dyspnœa in that it diminishes the irritability of the respiratory centre. This is not obtained by direct oxidation of camphor, but by the replacing of a hydrogen atom by a hydroxyl group in the camphor molecule. It occurs as a colorless, crystalline powder, which when fresh is odorless, soluble up to two per cent. in cold water, but in hot water or alcohol is much more soluble. Its solution is almost tasteless or slightly bitter; is neutral in reaction, and in exhibition of the fresh drug forms an absolutely clear solution. In the presence of light and moisture it readily changes its appearance and composition. Investigation as to the effect of this remedy upon the circulatory system and the temperature shows that its influence thereon is not worthy of mention. To be sure, the pulse rate diminishes to the extent of from ten to twelve beats per minute, but this slowing may be accounted for by the improvement of respiration following its use. It may be administered in compressed tablets with sugar of milk, each containing four grains of the active substance. For administration, to avoid gastric disturbance, the tablets may be dissolved in hot water and given in solution with syrup. Gelatin capsules form a better method of administration. The daily amount taken may be as much as thirty grains. The instances

of its use which are reported seem to confirm the statement made as to its properties. As a direct result of the relief of the dyspnœa, sleep is greater in amount and more restful.

"Oxidized Toxines" in the Treatment of Microbic Diseases.—Dr. George Stoker (*Journal of Laryngology, Rhinology, and Otology*, April) suggests the use of "oxidized toxines" in laryngeal phthisis and other microbial diseases. He says that it is reasonable to suppose that under healthy conditions certain micro-organisms may prove beneficial in maintaining health or promoting healing, but that under unhealthy conditions these same micro-organisms may prove detrimental to health or prevent healing, as witness the *Bacillus coli*, instanced by the late Professor Kanthack. It is also evident, he says, that the secretions or toxines produced by certain micro-organisms, which are in the first instance virulent and deadly, can be so altered as to prove beneficial, as is the case in, for instance, the bacillus of diphtheria. Dr. Stoker's contention is, that the most potent factor in bringing about such a change is the process of oxidation.

The author makes a broth cultivation of bacteria taken from the affected part. This is incubated for fourteen days in an air-tight flask, when a stream of oxygen is passed through the broth for several hours. The organisms are then removed by filtration, and the remaining fluid applied to the affected part as often as experience directs.

He has found special interest in this method in cases of true lupus, and in cases of wounds and ulcers infected with the *Bacillus pyocyaneus*. In cases of lupus the part is first scraped, to remove as far as possible all diseased tissue, and oxygen is then applied by means of a gutta-percha mask as soon as bleeding has stopped. In all such cases reactions have occurred—reactions of an essentially toxic nature. From this it is concluded that the toxines produced on the wounds are oxidized and so altered that, when absorbed, they become antagonistic to the original poison. Acting on this conclusion, oxidized toxines have been prepared and applied in various cases, lupoid and otherwise, with most beneficial results. These artificial oxidized toxines also produce reactions, not, however, so marked as those by the toxines generated on the wound. This may be accounted for by the fact that the chemical change takes place in the oxidizing flask, and not on the diseased surface.

The *Bacillus pyocyaneus* is, in the author's experience, the most persistent and most hostile to healing of any of the micro-organisms usually found in wounds or ulcers. He has known this bacillus to resist the usual germicides, including strong solutions of carbolic or boric acid, the double cyanides, and solution of perchloride of mercury (1 in 500).

If a stream of oxygen is passed through a sterile broth, says the author, no result is observed; if this same broth is inoculated with the *Bacillus pyocyaneus* and incubated without access of air in an air-tight flask for fourteen days, there is no change apparent beyond the usual cloudiness; but if a stream of oxygen is passed through the broth two important changes are observed: 1. The broth at once becomes of a green color, which deepens and intensifies as oxidation is continued. 2. The broth from being liquid becomes glutinous or semigelatinous, showing that the bacilli have modified the character of the broth, and that the oxygen has further altered the broth so modified.

The product of the bacilli plus oxygen is volatile; for if the stream of oxygen be discontinued after a few minutes, the broth will in a few hours resume its original color, but if the stream of oxygen is continued for a few hours the color becomes permanent. When the oxidized toxine is applied to the wounds or ulcers from which the bacilli were originally procured, the result is that after a short time the *Bacillus pyocyaneus* disappears, and only diplococci and staphylococci remain, as may be seen by reference to the slides under the microscopes. It would appear, therefore, that the surest germicide for the *Bacillus pyocyaneus* is its own oxidized toxine; and if this is true of one, why not of others?

The author thinks that in the face of these facts it is no longer possible to say that oxygen does not affect micro-organisms or their toxins; and he suggests that in cases of laryngeal phthisis one should proceed to take a culture from the affected parts, make an oxidized toxine, and apply it frequently.

The Therapeutic Uses of the Salts of Vanadium.—Lyonnet, Martz, and Martin (*Lyon medical*, March 19th) sum up the conclusion of their researches on this subject as follows: 1. The derivatives of vanadium possess an oxidizing power of extraordinary energy, for which power they are employed with great success in the industrial arts. 2. Metavanadate of sodium is a stable salt, soluble in water and easy to study. 3. This salt is very toxic. A rabbit is killed by the intravenous injection of seventeen milligrammes for each kilogramme of weight; the dog, by seventy-nine milligrammes for each kilogramme. The guinea-pig and the frog are also killed by subcutaneous injections. The animals die with symptoms of dyspnoea and convulsions. It has no apparent action on the heart. 4. *In vitro* the metavanadate of sodium acts very slightly on the digestive ferments, the sugar of the blood, yeasts, and microbes. 5. In spite of its toxicity, metavanadate of sodium may be administered to man *per os* without inconvenience, in quantities of from one to five milligrammes (about $\frac{1}{16}$ to $\frac{1}{32}$ grain) in twenty-four hours. It appears preferable to give this salt intermittently on two or three isolated days in the week. It is almost tasteless and is well supported by patients. 6. After the administration of this substance there is noted nearly always a speedy increase in the appetite, vigor, and weight. The amount of urine is slightly increased, the urea and the coefficient of nitrogenous oxidation are augmented. In diabetes the secretion of sugar is temporarily diminished. 7. Combustion is therefore rendered more active. Vanadate of sodium seems to give a spur to nutrition. It does not appear to act by merely oxidizing once for all the various substances of the organism. It would appear rather that after having given up oxygen to the tissues, it recovers it from them and the process begins anew. There would thus be a constant come-and-go movement between vanadic and hypovanadic acids. The vanadate would be a distributor of oxygen for the tissues, acting, so to speak, by virtue of its presence, in almost infinitesimal doses, after the manner of ferments. 8. The metavanadate of sodium has then, in the authors' opinion, a medicinal value superior to that of arsenic, and appears to them the *drug par excellence* for retarded nutrition and cachectic states. The authors have also experimented with a vanadate of iron and vanadate of lithium, and are investigating arseniovanadic acid, a preparation with the formula $\text{Vn}_2\text{O}_5 \cdot \text{As}_2\text{O}_5 \cdot 11\text{H}_2\text{O}$.

Proceedings of Societies.

SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

Meeting of December 14, 1898.

The President, Dr. WALTER B. JOHNSON, in the Chair.

(Continued from page 751.)

Retention of Urine.—Dr. RAMON GUITERAS read a paper on this subject.

Dr. ADOLPH RUPP said he would like to ask the reader of the paper as to one remark that he made: "When we have drawn off about two thirds of the urine from the bladder." In hospital and private practice the catheter was left in until the water ceased to flow. In most of the cases in private practice the urine was drawn off and that was the end of it. The more interesting cases were those that fell into the hands of the specialist, which the general practitioner did not see. In Charity Hospital in the genito-urinary wards he saw some interesting cases. He spoke of the case of a young fellow thirty years of age. Nothing could be passed into the urethra, and, as he did not wish to operate, the patient was put into a hot bath and kept there for five or six hours, but still the catheter could not be passed. Finally, the speaker suggested giving chloroform, and then under the anaesthesia passed a filiform and brought the water away. After that there was no more trouble. He wanted to know how one could tell that he had got about two thirds of the urine, or why one should leave a residuum. In some cases of retention the patient could be relieved in a medical way without any mechanical means. For instance, good-sized doses of salicylate of sodium would give relief without resorting to a catheter or putting a catheter into the hands of the patient.

Dr. HENRY H. SCHROEDER spoke of a class of cases occasionally seen, in which through neglect or ignorance the stricture scarcely allowed a filiform to pass. As a consequence there were a very offensive urine, badly diseased bladder, and an advanced pyelonephritis. He mentioned some cases in which he had used salol and other antisepsics eliminated by means of the urine, with only temporary benefit, the patients getting gradually into a critical condition. In two of the cases, after consultations, it was decided to take more radical measures, in view of the fact that the patients could not live much longer in the existing state of things. Under anaesthesia a filiform was passed and a tunneled sound introduced. This was followed by a catheter through which some urine was drawn. The operation was followed by complete retention of urine, which persisted in spite of all efforts for relief. Paracentesis was resorted to for two or three days, and then, as there seemed to be no prospect of the urine finding its way out by the urethra, a suprapubic incision was made. The patient died, however, so that the effort to produce relief and a period of what might have been well warranted for a few days. The speaker then stated that he would be considered beyond hope of relief, and that if we could confine our efforts to making a catheter.

Dr. GUITERAS said, in regard to Dr. RUPP's remarks, that it was impossible to draw out two thirds of the urine had been drawn off, and that he had said "what we estimate to be two thirds." A normal bladder would usually hold, even in the young, about a

half. Of course, one did find dilated bladders which held two quarts or more; but in cases of that kind one could outline the bladder and determine about how much urine there was in it approximately. It was considered in genito-urinary surgery the most dangerous thing to completely empty the bladder in cases of acute complete retention, as then the blood-vessels of the bladder became engorged, or, in other words, there was congestion, and congestion was the best predisposing cause of cystitis. One of the great difficulties in breaking a patient into catheter life was in knowing when and how to use the catheter. If there were retention of urine and congestion of the bladder wall, there might also be congested ureters and kidneys, and emptying the bladder might also set up an inflammation of these organs. In a great many cases where there was an obstructive cause of retention, there were cystitis, dilated kidneys, and perhaps pyelonephritis; and if one completely emptied the bladder, suppression of urine and death from uremia might follow. Cases of death from collapse had followed the complete emptying of the bladder. The treatment Dr. Rupp referred to in Charity Hospital, where they gave the patient a hot bath and afterward administered chloroform, and inserted a fine, soft-rubber catheter, was one of the ways of treating retention, although he thought it would be better not to give an anæsthetic unless absolutely necessary, and, in case it was, to use laughing gas. Morphine hypodermically would often relieve the spasm. It was much better to perform paracentesis than to force an instrument into the bladder the first time, unless it was to be followed immediately by an operation. In regard to Dr. Schroeder's case, if one could pass a filiform into the bladder, it was well to leave it in, and the next day it would probably be possible to introduce a small catheter. He thought a great deal of harm was done in cases of prostatic obstruction by handling the prostate too roughly; one could not handle these cases too gently.

Book Notices.

Nervous and Mental Diseases. By ARCHIBALD CHURCH, M. D., Professor of Clinical Neurology and of Mental Diseases and Medical Jurisprudence in the Northwestern University Medical School (the Chicago Medical College), Chicago, etc.; and FREDERICK PETERSON, M. D., Clinical Professor of Mental Diseases in the Woman's Medical College, New York, etc. With Three Hundred and Five Illustrations. Philadelphia: W. B. Saunders, 1899. Pp. 11 to 813. [Price, \$5.]

It is stated in the preface that "this book has been written for medical students and general practitioners. It makes no claim to be other than a carefully prepared text-book." Such a claim, modest in appearance, is in reality one of no little magnitude. To present in one volume the facts of two great subjects clearly, directly, briefly, and at the same time with thoroughness is an exacting task. Its successful accomplishment by Dr. Church and Dr. Peterson reflects great credit upon the knowledge and literary ability of these gentlemen. The book is not the joint work of two writers, but each author has contributed in his own special department. Dr. Church in neurology and Dr. Peterson in psychiatry. There is thus maintained the individuality of each, and the reader has the benefit of the

special experience of both. At the same time, the uniformity of plan is not affected, and the volume remains a compact, thorough, and modern presentation of the most recent conceptions of nervous and mental disease.

The subjects are treated with clearness, without the style being in the least abrupt or fragmentary—in fact, one only becomes conscious of the brevity, which is uniformly observed, upon noting how few pages are necessary for a clear and complete presentation of a pathological description, a clinical picture, or principles of treatment.

There is, withal, no lack of thoroughness. For the class of readers for which it was intended this treatise is abundantly adequate.

These qualities insure a successful future for this joint labor. To be clear, brief, and thorough, and at the same time authoritative, are merits which insure popularity. The long-suffering medical student and the practitioner not particularly identified with nervous or mental diseases will find in this volume a ready and reliable resource. It bears, furthermore, the mark of careful bookmaking from a publisher's point of view.

Syphilis. Von Dr. ISIDOR NEUMANN, o. ö. Professor der Dermatologie und Syphilis an der Universität Wien. Zweite Auflage. Mit 60 Abbildungen. Wien: Alfred Hölder, 1899. Pp. xv+852.

THE rapid appearance of the second edition of Dr. Neumann's book bespeaks not only the necessity which existed for an exhaustive monograph on this subject, but also the authoritative place occupied by the writings of the Vienna syphilographer. Certainly no living man is better qualified than he to speak *ex cathedra* of syphilis; and this volume reflects a fruitful experience, by personal contact and by literary research, with this "index of civilization." The book is a large one, having 852 pages, many of which are in fine print. But the subject is big, intertwined as it is with every branch of practical medicine and with most important sociological questions. Familiarity with it is essential to every medical man; and for that purpose the present volume is none too comprehensive.

Syphilis is here presented in all its phases and with its many side issues. The views which are expressed on moot points, such as the specific character of the hard chancre, the uselessness of operation upon it, the failure of attempts at animal inoculation, the unknown character of the virus, the best methods of treatment, etc., are the ones best established by the facts and most entitled to credence.

Dr. Neumann's production has taken its place as the modern monograph on syphilis. Its one drawback is a rather heavy style and a lack of clearness in places.

An Epitome of the History of Medicine. By ROSWELL PARK, A. M., M. D., Professor of Surgery in the Medical Department of the University of Buffalo, etc. Based upon a Course of Lectures delivered in the University of Buffalo. Second Edition. Illustrated with Portraits and other Engravings. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1899. Pp. xiv+370.

OUR readers will perhaps recall the fact that the first edition of this work had notice by us almost within the year. The opinion we then expressed of its merit has apparently become general, and we are far from feeling surprise at the early demand for a second edition. The

later edition differs from the earlier only in the correction of a few inaccuracies and in the addition of a chapter upon Iatrotheurgic Symbolism, which is both of interest and of value.

A Manual of Organic Materia Medica. Being a Guide to Materia Medica of the Vegetable and Animal Kingdoms. For the Use of Students, Druggists, Pharmacists, and Physicians. By JOHN M. MAISCHE, Ph. M., Phar. D., Late Professor of Materia Medica and Botany in the Philadelphia College of Pharmacy. Seventh Edition. Revised by HENRY C. C. MAISCHE, Ph. G., Ph. D., Professor of Materia Medica and Botany in the Medico-chirurgical College of Philadelphia, Department of Pharmacy. With Two Hundred and Eighty-five Illustrations. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. vi-17 to 523.

THE seventh edition of this well-known work is but a modernization of the sixth, the form and scope remaining unchanged and the volume being increased only by the few additions that progress has required. The work remains what it has been since its first appearance, an authority in its field.

Chemistry: General, Medical, and Pharmaceutical, including the Chemistry of the United States Pharmacopœia. A Manual on the Science of Chemistry, and its Application in Medicine and Pharmacy. By JOHN ATTFIELD, F.R.S., Ph.D., of the University of Tübingen, F.I.C., F.C.S., for Thirty-four Years Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, etc. Sixteenth Edition. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. xxii-17 to 780.

NO more need be said of the latest edition of this admirable work than to refer to the very thorough revision and modernizing which is apparent throughout. That so able a work should be perpetuated by frequent rejuvenation is a matter for self-congratulation by all who are students of chemistry. Sixteen editions are a sufficient warranty of the esteem wherein it is held.

BOOKS, ETC., RECEIVED.

The Nose and Throat and their Diseases. By LEONARD BROWNE, F.R.C.S.E., Senior Surgeon to the Central London Throat, Nose, and Ear Hospital, etc. With Special Assistance as follows: Anatomy, by MAYO COOGLIER, M.D., F.R.C.S.; Nervous Diseases, by JAMES CONNELL, M.D.; and Histopathology, by WYATT WINGGERS, M.R.C.S., Assistant Surgeon and Pathologist to the Central London Throat, Nose, and Ear Hospital. With Five Hundred and Fifty Illustrations in Color, etc. Designed and Executed by the Author. Fifth Edition, revised and rewritten. London: Baillière, Tindall, and Cox. Philadelphia: J. B. Lippincott Company, 1899. Pp. xxvi 967.

A Text-book of Anatomy. By AMERICAN ANATOMISTS. Edited by FREDERICK HENRY GARRISH, M.D., Professor of Anatomy in the Medical School of Maine, Bowdoin College. Illustrated with Nine Hundred and Forty-two Engravings in Black and Colors. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. 5 to 917. Price, \$6.50.

The Medical Complications, Accidents, and Sequelæ of Typhoid or Enteric Fever. By ROBERT ANTON-HOLZ,

M.D., B.Sc., Professor of Therapeutics in the Jefferson Medical College of Philadelphia, etc. With a Special Chapter on the Mental Disturbances following Typhoid Fever. By F. X. DORCUM, M.D., Clinical Professor of Diseases of the Nervous System in the Jefferson Medical College. Philadelphia and New York: Lea Brothers & Co., 1899. Pp. vi-17 to 286. [Price, \$2.10.]

The Surgery of the Head and Neck. By LEVI COOPER LANE, A.M., M.D. (Berol.), M.R.C.S. Eng., LL.D., Professor of Surgery in Cooper Medical College, San Francisco. Second Edition. Philadelphia: P. Blakiston, Son, & Co., 1899. Pp. xxx-7 to 1180. [Price, \$5.]

A Review of Recent Legal Decisions affecting Physicians, Dentists, Druggists, and the Public Health. Together with a Brief for the Prosecution of Unlicensed Practitioners of Medicine, Dentistry, or Pharmacy, with a Paper upon Manslaughter, Christian Science and the Law, and other Matter. By W. A. PURRINGTON, of the New York Bar, Counsel of the Dental Society of the State of New York, etc. New York: E. B. Treat & Co., 1899. Pp. 3 to 105. [Price, 50 cents.]

Golden Rules of Medical Practice. By ARTHUR HENRY EVANS, M.D., B.S. (Lond.), F.R.C.S. (Eng.), House Surgeon, Late House Physician and Resident Obstetric House Physician, Westminster Hospital, etc. Golden Rules Series, No. 4. London: Simpkin, Marshall, Hamilton, Kent, & Co., 1899. Pp. 3 to 51. [Price, 1s.]

Die laryngo- und rhinologischen Untersuchungsverfahren. Von Dr. Gustav ABELES, Assistent der Kaiser Franz Josef- (früher Mariahilfer) Ambulatoriums in Wien, praktischer Arzt. Mit 25 Abbildungen im Texte. Leipzig: C. G. Naumann, 1899. Pp. 156. [*Medizinische Bibliothek für praktische Ärzte*, Nr. 139-141.]

Die neuere Geschichte der Medizin. Kurz dargestellt von O. v. BOLLENSTERN, in Bremen. Leipzig: C. G. Naumann, 1899. Pp. vii 398. [*Medizinische Bibliothek für praktische Ärzte*, Nr. 142-147.]

Die Zuckerkrankheit. Von Dr. med. Otto HEDEL, pract. Arzt in Wiesbaden. Leipzig: C. G. Naumann, 1899. Pp. xvi 333. [*Medizinische Bibliothek für praktische Ärzte*, Nr. 148-152.]

New York Eye and Ear Infirmary Reports. Volume VIII. January, 1899.

Report of the Public Education Association of Philadelphia, made at the Eighteenth Annual Meeting.

The Twenty-seventh Annual Report of the Board of Directors of the Zoological Society of Philadelphia.

Medical and Surgical Reports of the Boston City Hospital. Tenth Series.

Annual Report of the Board of Health of the City of Winona, Minnesota. For the Year ending March 31, 1899.

The Differential Diagnosis of Pharyngeal and Esophageal Lesions and Dysphagia. By E. W. S. SMITH, M.D., of Philadelphia. [Reviewed in this *Journal*.] [*Medical Journal*.]

The Surgical Anatomy of the Human Ear. By GEORGE H. THORNTON, with Results of the Dissection of the Ear. By ROBERT CUSTER TUCK, M.D., of New York. [Reviewed in this *Journal*.] [*Medical Journal*.]

Syphilitic Insanity. By A. P. CROFT, with Especial Reference to the Pathology. By GEORGE F. COOPER. By CHARLES K. MOTT, M.D., of Philadelphia. [Reviewed in this *Journal*.] [*Medical Journal*.]

The Influence of Turbinal Hypertrophy upon the Pharynx. By Lewis S. Somers, M. D. [Reprinted from the *University Medical Magazine*.]

Clinical Notes on Nosophen, Antinosine, and Nosophen Gauze. By John S. Perekhan, M. D., of Chicago. [Reprinted from the *Chicago Medical Recorder*.]

Ueber die Wirkungen und die Indikationen der Traubenkur. Von Dr. Bemo Laquer, in Wiesbaden. [Sonderabdruck aus der *Zeitschrift für diätetische und physikalische Therapie*.]

New Inventions, etc.

A MODIFIED CHLOROFORM INHALER.

By FREDERIC GRIFFITH, M. D.,
NEW YORK.

A MODIFIED chloroform inhaler which I have made from a piece of spring wire may have a point of simplicity deserving of notice.

After twisting the wire into shape, the ends around the base (B-C) were all left long and cut with pointed ends by a twist with the pliers.

The need of sewing the gauze over and the use of the extra wire holder is thus made unnecessary.

A square of double thickness of gauze is cut large enough to cover the wire frame. A hole is made near the selvage end; this passes over and is held at shoulder (A); then the gauze may be readily fastened around the hooks and trimmed.

The frayed ends tucked in will take up any excess of chloroform which may run down from the use of such thin material. A plentiful supply of air is thus not impeded during the anaesthesia.

15 WEST FIFTY-EIGHT STREET.

Miscellany.

The American Orthopaedic Association.—The thirtieth annual meeting will be held in New York on Wednesday, May 31st, and Thursday and Friday, June 1st and 2d, under the presidency of Dr. W. R. Townsend. In addition to the president's address, the programme includes the following papers: Rotation of the Spine in the So-called Lateral Curvature: its Causes and Treatment, by Mr. W. Adams; Clinical Notes relating to the Operation of Arthrodesis, by Dr. B. Bartow; The Forceful Correction of Lateral Curvature, by Dr. E. H. Bradford and Dr. E. G. Brackett, of Boston; On the Treatment of Lateral Curvature of the Spine, by Mr. Bernard E. Brodhurst; Further Observations of Adenoids in Orthopaedic Deformities, by Dr. F. S.

Coolidge, of Chicago; The Operative Treatment of Congenital Luxation of the Hip, by Dr. G. G. Davis, of Philadelphia; *Brisement forcé*, with Immediate Massage in the Ankylosis, following Tuberculous Osteitis of the Knee, by Dr. V. P. Gibney; A Study of Pott's Paraplegia, as effected by Correction of the Spinal Deformity, by Dr. Joel E. Goldthwait, of Boston; A Treatment for Acute Serous Synovitis, permitting Joint Functions, by Dr. Philip Hoffmann, of St. Louis; Pigeon Toe, by Dr. W. Barton Hopkins, of Philadelphia; Prothesis, a Branch of Orthopaedic Practice, by Dr. A. B. Judson; The Cause of Failure after Phelps's Operation for Clubfoot, by Dr. Daniel La Ferte, of Detroit; Joint Changes in Haemophilia, by Dr. Robert W. Lovett, of Boston; Heat as a Therapeutic Measure, by Dr. S. L. McCurdy, of Pittsburgh; Surgical Intervention in Spastic Paralysis, by Dr. B. E. McKenzie; Congenital Dislocation of the Hip, by Dr. T. Halsted Myers; A Preliminary Report of the Study of Lateral Curvature, by Dr. A. M. Phelps; Degeneracy as a Causative Factor in the Production of Scoliosis, by Dr. John Ridlon, of Chicago; A Study of the Musculo-neural Elements in Chronic Joint Disease, by Dr. N. M. Shaffer; Position Symptoms in Joint Disease, by Dr. H. M. Sherman, of San Francisco; The Recording of Lateral Curvature of the Spine, by Mr. E. Noble Smith; The Conservative Surgical Treatment of Tuberculous Diseases of the Joints, by Dr. Clarence L. Starr; Pointers on the Leather Splint, by Dr. A. J. Steele, of St. Louis; The Report of a Case of Dorsal Dislocation of the Hip, occurring Spontaneously during the Course of an Acute Osteomyelitis of the Neck and Shaft of the Femur, by Dr. William J. Taylor, of Philadelphia; Sentences selected from the Orthopaedic Writings of C. Fayette Taylor, M. D., by Dr. Henry Ling Taylor; The Liver in Rickets from a Clinical Standpoint, by Dr. R. T. Taylor, of Baltimore; Some Clinical Features of Rheumatoid Arthritis—A Summer Plaster-of-Paris Jacket, by Dr. R. T. Taylor, of Baltimore, and Dr. S. H. McKim, of Washington; Some Post-paralytic Deformities and their Treatment, by Dr. Jacob Teschner; Congenital Deformities of the Spine, by Dr. Augustus Thorndike, of Boston; Some Remarks on the Class Method of Gymnastic Treatment in Lateral Curvature, by Dr. Walter Truslow, of Brooklyn; The Diagnostic Value of Radiography in Orthopaedic and General Surgery, by Dr. L. A. Weigel, of Rochester; Further Observations on the Treatment of Congenital Dislocation of the Hip, by Dr. Royal Whitman; Forceful Correction of Spinal Deformities under Anaesthesia, by Dr. W. E. Wirt, of Cleveland; and Joint Infection in Typhoid Fever, by Dr. Charles W. Wilson, of Vineland, N. J.

The Hospital Graduates' Club will give its fourteenth anniversary dinner on Saturday evening, June 3d, at the Union Square Hotel.

The Seeming Immunity of Street Cleaners and Prostitutes to the Plague.—The *Cincinnati Clinic* for May 13th, referring to the *Lancet* for February, date not named, calls attention to the fact that the plague, which has already carried off some three hundred thousand people in Bombay, has left the street cleaners and prostitutes comparatively untouched. Of the lowest caste of Indian population, whose very occupation leads them into squalor and filth, the street cleaners, only twenty-one persons out of about a thousand have been affected in three years; while out of some seven thou-

sand prostitutes of various nationalities but one case of bubonic plague has been discovered. These singular facts, if such they are, seem hardly explicable on any known grounds. One would expect that these two classes would be among the greatest sufferers.

The University of Michigan.—The annual commencement will take place on June 22d. Besides the usual ante-commencement ceremonies, the medical department will have a special programme for its friends and the alumni, an unusual number of whom have signified their intention of being present. All the laboratories will be open on the 19th, 20th, and 21st, demonstrations will be made on special subjects in anatomy, histology, pathological anatomy, pharmacology, bacteriology, and medical electricity, and clinics will be given in each clinical branch. We are informed that these exercises will not interfere with those of the general programme or with each other.

The American Dermatological Association.—The twenty-third annual meeting will be held in Philadelphia on Tuesday and Wednesday, May 30th and 31st, and Thursday, June 1st, under the presidency of Dr. John A. Fordyce. In addition to the president's address, the programme contains the following titles: Epithelioma as a Sequence of Psoriasis, and the Probability of its Arsenical Origin, by Dr. Milton B. Hartzell, of Philadelphia; Imperfect or Deficient Urinary Secretion as observed in Connection with Certain Diseases of the Skin, by Dr. L. Duncan Bulkley; Two Epidemics of Alopecia Areata in an Asylum for Girls, by Dr. John T. Bowen, of Boston; A Report of a Case of Congenital Dermatitis Herpetiformis and almost Complete Absence of Finger and Toe Nails, by Dr. Samuel Sherwell, of Brooklyn; A Maculo-anæsthetic Lepidre of the Palm, by Dr. D. W. Montgomery, of San Francisco; A Report on Some Cases of Bilateral Linear Nævus, or So-called Nævus Unius Lateris, by Dr. Isadore Dyer, of New Orleans; The Demonstration of Ringworm and Favus Cultures, by Dr. Sigmund Pollitzer; The Sensory Disorders of Leprosy, by Dr. Prince A. Morrow; Remarks on the Treatment of Scabies, by Dr. Samuel Sherwell; A Contribution to the Histopathology of Epidermolysis Bullosa, by Dr. George T. Elliot; A Contribution to the Study of Blastomyctic Dermatitis, by Dr. James N. Hyde, of Chicago; and Necrotic Granuloma and Indurated Erythema in the same subject, by Dr. James C. Johnston. There will be a general discussion on the rôle of pus organisms in diseases of the skin, which is to be opened by Dr. T. Carson Gilchrist, of Baltimore, and Dr. George T. Elliot.

The "Bemiss Rules" for the Diagnosis of Yellow Fever.—The Louisiana State board of health has lately issued a circular embodying the rules arranged by the late Professor Samuel Bemiss. The circular is substantially as follows:

The following groups of symptoms shall be considered to indicate yellow fever:

Group 1. A person after a sudden attack of fever of one paroxysm, attended with marked congestion or blood stasis of the capillaries of the conjunctivæ, conjunctivæ, and gums, with a history of previous exposure to infection, and no history of a previous attack of yellow fever.

Group 2. A person after a sudden attack has a history of one paroxysm, followed by unusual prostration, albuminous urine, yellowness of the conjunctivæ, and

and having no positively authenticated history of previous attack of yellow fever.

Group 3.—A person has a fever of one paroxysm, albuminous urine, black vomit, suppression of urine, and a general hæmorrhagic tendency under circumstances where exposure to infection is a possibility.

Suspicious Cases of Yellow Fever.—The following symptoms associated with fever of one paroxysm in a patient who has been apparently exposed to infection, and has never had yellow fever, shall be held to justify in either of the six following cases a suspicion of this disease—viz.: 1. Suddenness of attack, either with violent pain in the head and back, injected eyes and face, or marked congestion of the superficial capillaries. 2. Want of that correlation between pulse and temperature usual to other forms of fever. 3. Albuminous urine. 4. Black vomit. 5. General hæmorrhagic tendency. 6. Yellowness of the skin.

The following cases shall also be suspicious: 7. Any case respecting which reputable and experienced physicians disagree as to whether the disease is or is not yellow fever. 8. Any case respecting which efforts are made to conceal its existence, full history, and true nature.

In the event of death in a suspicious case a post-mortem examination should be made, when practicable. Both before and after death yellow fever is especially and preeminently characterized by the fact that it is *par excellence* a hæmorrhagic fever, marked by capillary congestion and its sequelæ; hence post-mortem evidence of a general hæmorrhagic tendency in internal organs, especially in the digestive, in preference to the urinary tract, shall be held to confirm the suspicion.

The Third District Branch of the New York State Medical Association.—The fifteenth annual session will be held in Elmira, on Thursday, June 1st, under the presidency of Dr. F. D. Reese, of Cortland. In addition to the president's address the following papers will be presented: A Case of Extra-uterine Gestation, by Dr. R. Aberdeen, of Syracuse; Nature and Art in the Cure of Disease, by Dr. J. M. Farrington, of Banghamton; Pneumonia in Children, by Dr. H. S. Braman, of Homer; The Medical Expert Witness and his Future, by Dr. T. A. Wales, of Elmira; The Value of Pathological Investigations in Medico-legal Examinations, by Dr. F. Ferguson; Displacements of the Spleen, by Dr. E. W. Higgins, of Cortland; Glenard's Disease, by Dr. L. D. Farnham, of Banghamton; Displacements of the Pelvic Organs, by Dr. E. H. Wiggins; Floating Kidney, by Dr. Joseph D. Bryant; Operations for Strabismus, by Dr. U. H. Brown, of Syracuse; Some Observations in the Care and Treatment of Disease in the American and Cuban Hospitals, by Dr. E. W. Ross, of Elmira; Some Lessons from Colloid Cancer in the Adipon, by Dr. E. D. Ferguson, of Troy; Personal Therapeutic Observations, by Dr. H. D. Dolan, of Syracuse; A Report of a Case of Myxodema, by Dr. John C. Fisher, of Elmira; A Case of Exophthalmic Goitre, with Remarks, by Dr. W. L. Ayer, of Oswego; Some of the Suggestive Cases of the Year, by Dr. J. J. B. of Newburgh; and A Case of Cesarean Section, by Dr. R. Aberdeen, of Syracuse.

The Academy of Medicine of Paris.—We learn from the *Chicago Medical Record* for May that Earl Lester and Dr. Koch have been elected to the associateship of the academy, which is the highest honor of the medical profession of France can bestow.

The Louisiana State Medical Society held its annual meeting in New Orleans on May 16th, 17th, and 18th, when the following officers were elected: President, Dr. W. G. Owen, of White Castle, Louisiana; vice-presidents, Dr. Felix Formento, Dr. F. W. Parham, Dr. W. A. Holloway, Dr. T. E. Schumpert, Dr. J. B. Bonney, and Dr. G. C. Mouton; recording secretary, Dr. H. B. Gessner, of New Orleans; treasurer and librarian, Dr. H. S. Cocram, of New Orleans.

Not so Unlikely Either!—The *Doctor's Factotum* for May and June quotes the following from the *Pittsburgh Chronicle*:

"Now, I suppose," remarked Mrs. Snaggs, "that the surgeons of the army are attached to the medical corps."

"Your supposition does you great credit," replied Mr. Snaggs sarcastically. "It's a wonder you didn't imagine that doctors joined the army for the purpose of building bridges or going up in balloons. Where should army surgeons be, except in the medical corps?"

"Well, I thought that they might possibly belong to the lancets."

The National Confederation of State Medical Examining and Licensing Boards.—The ninth annual meeting will be held in Columbus, Ohio, on Monday, June 5th, under the presidency of Dr. William Warren Potter, of Buffalo. The programme includes the following titles: Address of welcome, by the Hon. Asa S. Bushnell, of Ohio; address of welcome, on the part of the medical profession of Ohio, by Dr. Charles A. L. Reed, of Cincinnati; Response, by Dr. William Bailey, of Louisville; Educational Foundation for a Physician's Special Training, by President James H. Canfield, of the Ohio State University; The Results of the Medical Law of New Jersey, by Dr. Edmund L. B. Godfrey, of Camden, N. J.; The Results of the Medical Law of Kentucky, by Dr. Joseph M. Mathews, of Louisville; The Tennessee Method, by Dr. Thomas J. Hoppel, of Trenton, Tenn.; The Old and the New in Nebraska, by Dr. Benjamin F. Crummer, of Omaha; The Medical Law of New Mexico, by Dr. William R. Tipton, of Las Vegas, N. M.; Thoughts on Preliminary Education, by Dr. Augustus Korndorfer, of Philadelphia; The Unifying Influence of the Three-board System, by Dr. H. M. Paine, of Albany; Cooperation between the Legal Representatives of the Various State Boards, by the Hon. Ralph E. Westfall, of Columbus, Ohio; and On the Preparation of Questions, by Dr. Edward Cranch, of Erie, Pa.

The Skene Hospital for Women.—It is announced that the directors of the projected hospital for self-supporting women have applied to the State board of charities for permission to incorporate.

A Curious Blunder by the Board of Aldermen.—The *New York Times* recently said:

"Not much is to be expected, of course, from our board of aldermen in the way of caution or accuracy in the use of words or the construction of sentences, but surely there must be at least a few men among the city fathers who could have given a little more sense to the first 'whereas' of a resolution sent by them recently to the board of health. That very well intentioned document began: 'Whereas, The practice of healing and curing the sick by unlicensed persons in the city of New York has become an evil which should be stamped out.' Here is an admission of all that is

claimed by the followers and practitioners of 'Christian Science,' 'voodooism,' and every other squalid superstition that has been spawned by ignorance and thriven on credulity. If the 'unlicensed persons' are guilty only of 'the practice of healing and curing the sick' they should all be licensed at once. As a matter of fact, they do no such thing; they only pretend to do it, nine times out of ten, and the tenth time they merely effect what any man can and every man does effect when he tells a friend to cheer up and think of something else than aches and pains. No, it is not the practice of healing and curing the sick that should be stamped out, but the practices of making the sick worse or dead, of swindling folks out of their money and brains, and of spreading infection by the stupid neglect of the commonest sanitary precautions."

The Woman's Hospital.—It is announced that Mr. Russell Sage has lately contributed \$50,000 to the fund for providing new buildings for the hospital.

The Elected American Fellow of the Royal College of Surgeons of England.—Under this heading the *Lancet* for May 13th says that the admission by election of an American surgeon to the fellowship of the Royal College of Surgeons of England at any time would be an interesting event. It is especially so at the present period when in the evolution of history a new recognition is being given everywhere to the essential alliance between England and the United States. In no sphere is this more important or more seemly than in the serene atmosphere of science, and in no branch of science more than in that of medicine. The professors of this branch on both sides of the Atlantic have long vied with each other in every demonstration of friendship and hospitality. We offer our congratulations to Frederic Shepard Dennis, M. D., professor of the principles and practice of surgery in the Bellevue Hospital Medical College, etc., to whom the unprecedented honor, as an American member of the college of twenty years' standing, of election to the fellowship has fallen. The election is not more honorable to Professor Dennis than it is creditable to the college. Few men combine the qualities and the merits of an elected fellow more than he does. His personal devotion to surgery, both as a teacher and a practitioner, and the embodiment in him of all that completes our conception of a genial American gentleman point him out as worthy to receive the compliment paid to him by his college. It is to this genial quality of his nature that he owes not only his large circle of friends in Great Britain and other European countries, but the fact that he has been able to associate with himself as editor so many distinguished compatriots in the compilation of his splendid *System of Surgery*, written throughout by American surgeons.

Medical Men and the Royal Society of London.—It is gratifying to notice the increasing proportion of members of the medical profession who attain the English blue ribbon of scientific distinction, the fellowship of the Royal Society. According to the *British Medical Journal* for May 13th, among this year's selections are to be found the names of Dr. Head, Dr. Starling, Dr. Windle, and Major Bruce, M. B., of the Royal Army Medical Corps.

The Manhattan Eye and Ear Hospital.—We are informed that Dr. H. Hovle Butts was recently appointed surgeon to the throat department of this institution.

Original Communications.

THE DOCTOR OUTSIDE OF MEDICINE.*

By WILLIAM L. STOWELL, M.D.

In 1626 Peter Minuit bartered articles worth twenty-four dollars for Manhattan Island. It is now assessed for more than two billion dollars. Then there was no physician on the island; now there are three thousand dividing the medical honors and striving to divide the dollars. "Each man in his time plays many parts," and the parts played by our profession may well occupy us for a little time.

Perhaps the earliest genuine doctor to arrive was Peter Van der Linde, who came in 1638. When physic was slow he inspected tobacco, and gave part of his time to school teaching. He was also clerk of the church. He could not have had all the obstetric work, because during his time Lysbert Dirksen was town midwife and lived in a house built at public expense. Her successor was voted one hundred guilders (thirty-eight dollars) annually to attend the poor.

About this time (1638-1647) there was in the council of Governor-General Kieft, Dr. John de la Montagne, "a man of intelligence and decision of character," a Protestant refugee from France, who had gone to Holland, and thence here. We find the colonists waging war against the Indians under "command of the indefatigable Montagne," and he later signs the peace treaty with them. There were at this time only a hundred white men on the island. One of them was Surgeon Hans Kierstede, from Saxony, who married Sara, daughter of Annetje Janse, "the famous midwife." This worthy pair had ten children, and so did what they could for the white population. More than that, Surgeon Kierstede was a director for the new church and got up a sort of festival where the guests became very full of good brew. When they were in good spirits he started a subscription for the new church, and the liberal pledges seem to have been all paid when the men were sobered. The property of this same Annetje Janse was the beginning of the great wealth of Trinity Church.

Surgeon Paulus Van der Beeck (1643) becomes rich by farming in Breuckeln, is tax collector and ferry master, and makes people wait for the boat "half a day and night."

Surgeon Jacob Varanger (1651) grows tired of being his own importer and consumer, so petition the council to pay "for the use of his medicament," and to raise his salary as physician to the trading company. Varanger is claimed as one of the founders of the first hospital, yet his name is not in the list of twenty "great

citizens," but among the two hundred and four "small citizens."

A little later on (1657) another composite doctor arrives—Samuel Megapolensis, son of Reverend Megapolensis. He is a Harvard graduate, who studied theology in Utrecht, and upon his return was appointed pastor of the church. He continued the rare art of both preaching and practising, and also did his part in politics, as appears from his being one of the commissioners at the English capitulation (1664).

In those days the palisade was along the present Wall Street. The only remaining relic of these early Dutch times is a portion of the foundation walls of 71 and 73 Pearl Street.

Those who died were buried just north of Bowling Green.

In 1666 Peter Harris, both physician and surgeon, was authorized to "exercise his art."

The term surgeon had been applied to ships' barbers, and had not the honor we now give it.

Gaudineau (1686), a Huguenot, also signs himself *chirurgo-physician*. He appears as lieutenant under Dongan in the French and Indian War (1708). There may be no significance in names, but it is curious to note that the first autopsy was held (1691) upon the body of Governor Slaughter, whose sudden death was thought to be due to poisoning. Dr. Johannes Kerfbyle, of Leyden, officiated.

The doctors did some fighting, not with Indians, as appears from the duel between Governor Dongan's nephew Thomas and Dr. John Livingston. The latter was killed and Dongan convicted of manslaughter.

In 1705 law and medicine combined in the person of Dr. Bridges, for a brief time chief justice.

In early days slavery flourished here, and a slave market was established in 1709 at the foot of Wall Street. Dr. Dupay was a slave owner, for we find that he wants £55 for a negro wench nineteen years old whom he had brought up from infancy. She did not like being sold on approval, and a few years later is again offered for sale, "as she has a great itch for running away."

Quarantine was hastily established, in 1710, on Governor's Island, then Mutton Island. Three thousand German Lutherans had left Plamotta to come here to make tar, cut masts, etc. Four hundred and seventy of them were buried at sea. The council was dismayed when the large remainder arrived, and, "fearing distempers," appointed Dr. Garrin, Dr. Law, and Dr. Moore to inspect the immigrants. Carpenters were also sent to build huts for them.

In 1725 Bedloe's Island was used as a quarantine for small-pox patients from Madeira.

About 1735 an almshouse, a public workhouse and house of correction, was built in the fields or park. It was on the site of the present city hall. Here slaves

* Read before the Society of the Alumni of the City Charities Hospital, February 9, 1899.

were kept for correction and the poor sheltered. Besides a salary, the keeper received fees from all who entered or were discharged, and 1s. 6d. for whipping. In 1764 the keeper was allowed £20 extra, as there had been no whipper for some time.

The second floor room on the Broadway side was the hospital ward, containing six beds. Dr. John Van Beuren was in charge on a salary of £100 a year.

It was here that Dr. Beckman Van Beuren introduced vaccination in the face of much opposition.

Dr. Gerardus Beekman, as president of the council, filled the executive chair in 1710 until the new governor arrived. He was a wealthy landholder, lieutenant-colonel of militia, etc. He was "the great gunner who shot a deer in city common, the antlers of which are still preserved in the family." He was one of the eight men condemned with Leisler when the latter was executed for treason in refusing to give up the fort. The doctor wrote to the governor that he wished to visit some patients on Long Island that were "very dangerous." Having leave to go, he neglected to come back to be executed.

Upon the arrival of Governor Clinton, in 1743, George Clarke returned to England said to be worth £100,000, "so profitable was it to rule New York." Ten years later Sir Danvers was governor. He had been deranged by grief at the loss of his wife, and two days after arriving here hanged himself from the fence in Mr. Murray's garden. Dr. Magraw, "the best physician in town," had ordered him sack and whey the day before, but he had refused it, telling the servant to prepare broth. Mr. Murray seemed to think this a sure evidence of madness. In 1743, Dr. McGrath introduced free cold bathing for the cure of fevers. He was an unrefined, captious man who was himself often "in hot water." These were troublous days in the colony. Small-pox and yellow fever prevailed (1737 and 1739), the Jews were disfranchised (1738), and thirty-four negroes and whites were executed for a plot to burn the city (1741).

About this time (1745) Dr. John Nichol died. He was an active practitioner and useful man, a member of the governor's council. In the same year Mr. John Dupuy, M. D., the man midwife, died, of whom the paper stated, "in which loss it may be truly said, as of Goliath's sword, 'there was none like unto him.'"

The most conspicuous physician of the last century was probably Cadwallader Colden (1688-1776). He was a Scotchman by birth. Wilson calls him "one of the ablest men in the province," and well he may. He graduated from the University of Edinburgh, studied medicine in London, and practised the same in Philadelphia for several years. Governor Hunter induced him to come to New York and made him first surveyor general in the colonies. The governor suffered much from sciatica, and finally returned home. In a letter he says: "I have no hope of ease on this side, having try'd

all remedies, Christian and Pagan, Polemical, Chymical, and Whimsical, to no purpose. Aix-la-Chapelle is all my present comfort." Colden's favorite study was botany, and he sent to Linnæus three or four hundred American plants. His pen was ever busy. He wrote on yellow fever, a *History of the Five Indian Nations of Canada*, and numerous scientific articles. He was for fifty years in his Majesty's council, and for twelve years lieutenant-governor. On account of the stamp act in 1765 a procession of citizens burned in effigy Colden and the devil; however, at another time fifty-six merchants congratulated him on his administration. At one time he had a country seat near Newburg, and again a large farm on Long Island. His intellectual capacity and attainments were great and various, one biographer saying that he was "known in the scientific and literary world as a physician, botanist, astronomer, and historian." He was the first to suggest the formation of the American Philosophical Society. He was loyal to the crown all his life, and died at the ripe age of eighty-eight years, in 1776, just after the English occupied New York.

The revolutionary period supplies medical anecdotes as well as war history. Dr. James Beckman erected a house in 1764 upon the bluff above East River at what is now Fifty-second Street. It stood there until 1874. This is a familiar spot to us of Charity Hospital. This historic house was at times occupied by such notables as General Howe, Sir Henry Clinton, and Madame de Riedesel. In the greenhouse there Nathan Hale was tried as a spy on September 21, 1776. He was then taken to City Hall Park and executed, not far from where his statue now stands.

The most important day this country ever saw was July 4, 1776, when the delegates from the thirteen colonies assembled in congress and declared American independence. All the fifty-six delegates present signed, and five of them were physicians. They were as follows:

Lyman Hall, from Georgia, a successful practitioner, afterward governor.

Benjamin Rush, graduate of Princeton when fifteen years old, who became professor of chemistry in the College of Philadelphia when twenty-four years old. He was surgeon-general of the hospitals during the war, and for the last fourteen years of his life treasurer of the United States Mint.

Oliver Woolcott, of Connecticut, was major-general in the army and held many high public offices, including that of governor. He and Hall were classmates in Yale in 1717.

Josiah Bartlett, of New Hampshire, was a "noble patriot"; for ten years in legislature and congress, governor of his State, justice of the supreme court, and first president of the State Medical Society.

The last signer was Dr. Mathew Thornton, from Londonderry, New Hampshire. He was a practitioner

and "most ardent patriot," whose monument bears the simple inscription "An honest man."

New York sent few doctors to the war, but among these zealous patriots are mentioned James Brewer, Moses Younglove, Ebenezer White, and Daniel Menema. She had seventeen original members in the Society of Cincinnati.

In 1790 congress removed from City Hall, New York, to Philadelphia. On October 14th of that year the medical society was allowed to use the council chamber for its meeting. There Dr. Nicholas Romaine gave medical lectures a year or two later.

At that time the medical society numbered twenty-eight members. Among the noteworthy men were Dr. John Bard and his son, Dr. Samuel Bard, who operated upon the carbuncle that afflicted George Washington.

Dr. John Bard (1716-1799) was a very eminent man, noted for his urbanity of manner as well as great learning. He established the first quarantine at Bedloe's Island, and was first president of the New York Medical Society organized in 1788. He was usually dressed in a red coat and cocked hat and carried a gold-headed cane. He drove in a low phaeton and was accompanied by a colored servant.

Samuel Bard (1742-1821), son of John, graduated at Columbia, and took his M. D. in Edinburgh. He organized the first medical school with Columbia, then King's College, and in 1769 took the chair of physic. He was dean of the faculty.

Dr. John Cochrane was evidently a man of wealth, as he lived on Broadway and entertained the generals of the army in a royal manner (Lamb).

No one enjoyed a higher social position and influence at this time than Mrs. John Jay. On one date, her only guests at dinner were Dr. and Mrs. John Charlton. Charlton was an English surgeon from the court of George III, who came with the army. He married Mary de Peyster. He usually rode on horseback, but practised little. In 1795 yellow fever again raged. The cabin boy and surgeon of a West Indian ship were the first to die. The disease spread, only to be checked by the frosts of November. Governor Jay then set Thursday, November 26th, as Thanksgiving day, as had previously been done in Massachusetts. More than fifteen hundred persons had died of the population of fifty thousand. This scourge resulted in underground sewers being begun. At this time there were one hundred students in Columbia and fifty more studying medicine.

Professor McMaster, writing on yellow fever, gives this interesting picture: "If the purchaser of the vinegar (for prevention) were a nervous man and tormented with hourly fear of being stricken with the fever, the spectacle he presented as he sallied forth to buy was most pitiable. As he shut his house door he was careful to have a piece of tarred rope in either hand, a sponge wet with camphor at the nose, and in his pocket a hand-

kerchief well soaked in the last preventive of which he had heard. . . . If he were so unhappy as to meet a friend on the way, neither shook hands, but exchanging a few words at a distance, each sought, bowing and scraping, to get to the windward of the other as he passed. When at last the shop was reached, nothing could induce him to enter while another stood at the counter, or was seen approaching on the street" (Wilson).

April 13, 1788, was the date of the "Doctors' Riot." This was caused by some inquisitive boys discovering the hospital doctors dissecting. They spread ghastly tales and soon had an angry mob after the young medics. The doctors sought safety in the jail, but barely escaped being removed from there. Dr. Hicks was hiding behind the chimney of his preceptor's house (Dr. Cochrane) while the mob were below, looking for him and evidences of his dissecting. The trouble lasted part of two or three days and was only quelled by the militia. Baron Steuben and Secretary Jay were endeavoring to quiet the mob by speeches when both were injured by flying missiles. Steuben was just praying that the soldiers should not be allowed to shoot when he was hit upon the head with a brick. As he fell he cried out, "Fire, Governor, fire!" and it was done.

Nicholas Romayne was a native New Yorker, 1765-1817. His weight of three hundred pounds did not affect his activity. He was "vested with almost all the honors the medical profession can bestow." He could upon invitation "lecture on the aphorisms of Hippocrates, unfold the structure of the brain, expound the philosophy of paludal diseases, or discourse on the plant which Clausius cherished." He was "at all times assiduous in civic pursuits and closet studies," a type of what a physician should be to a community.

Dr. Hugh Williamson (1735-1819) was another man of many gifts. He was ordained to preach, but gave up because of his health. He studied medicine in Edinburgh and Utrecht and practised successfully in Philadelphia. He was surgeon in the army, member of the North Carolina House of Commons, delegate to the convention to frame the Constitution, and was elected as a federalist to the first congress.

In Philadelphia he was professor of mathematics and one of a commission to observe the transit of Venus and Mercury.

Seventeen hundred and ninety-eight was marked by the invention of the steamboat. In March of that year Dr. Samuel L. Mitchell, then a representative in the legislature, introduced an act granting the exclusive right to navigate the New York waters by fire or steam for twenty years. The bill was passed very much as a joke. In April, 1807, Fulton actually made the trip from New York to Albany in the *Clermont* at the rate of five miles an hour. Dr. Mitchell was one of the passengers, and, as Golden was backing the scheme, he was most probably there also.

The most remarkable man of his time was Samuel Latham Mitchell, M. D., LL. D. (1764-1831). He graduated in medicine in Edinburgh, and returning here studied law with Chief-Justice Yates.

For twenty years he was visiting physician to New York Hospital. As a teacher, he was professor of chemistry and natural history in Columbia, professor of botany and materia medica in the College of Physicians and Surgeons, and one of the faculty of the Rutgers Medical School. His analysis of the Saratoga mineral waters helped their fame.

In 1796 he made a geological and mineralogical tour of the State, the published results of which laid the basis of his European reputation.

In 1797, together with Dr. Edward Miller and Dr. Elisha H. Smith, he founded (and for sixteen years edited) the *Medical Repository*, the first medical journal in this country.

His knowledge of the Indians was thorough. When they gave exhibitions at the Elgin Gardens he would translate their war songs; and because of his legal knowledge he was sent to make a treaty with them.

In politics he was in the State legislature working hard with Cadwallader Colden and Governor De Witt Clinton for the Erie Canal. In 1825 it was opened with the greatest naval fête the city had ever witnessed. Dr. Mitchell had procured bottles of water from the thirteen largest rivers in the world—Ganges, Nile, Mississippi, Amazon, etc.—and united them all in this artificial waterway. The doctor counted it the proudest day of his life when the inland lakes and ocean were united in “indissoluble marriage.” It cost \$7,602,000 then. We heard more about its cost last autumn. With Williams we find him working for the furtherance of West Point Military Academy. As United States senator he puts his energies into improved quarantine laws. With the ever-active Colden and others he established the Deaf and Dumb Institute. When State aid was wanted for the Botanical Gardens at Fiftieth Street, he talked for hours to the legislature, and that without special preparation. Naturally, he was among the incorporators of the Society for the Establishment of Free Schools in 1805.

Socially he was a delightful companion, not an abstract philosopher. He was Sachem of Tammany Society, was an active member of nearly all the learned societies of the world, and yet found time to preside over the “Krout Club,” or discuss conchology with Dr. Samuel Akerly, his brother-in-law.

His writings include *Theory of the Earth and Solar System*, *Phosphorescence of the Ocean*, *Anatomy and Physiology of the Shark*, a description of the fishes about New York (one hundred and sixty-six varieties), and *The Ethnology of the Indian*.

It is little wonder that Dr. Francis called him “the Nestor of American science.”

In St. Paul's churchyard at Vesey Street, on the

Broadway side, there stands near the fence a large monument which you have probably all seen, but perhaps not stopped to observe. It is that of the Irish patriot who made this his adopted home. Dr. William James Macnevin (1763-1841) was educated in Vienna, practised in Dublin, traveled in and wrote of Switzerland, and spent four years in an Irish jail. “He had no prison house; worth, freedom, Wisdom still can walk at large, though bolts and bars, and walls of adamant may intervene.” He translated from the original Gaelic, and compiled a French grammar for the children of Thomas Addis Emmet, his fellow prisoner.

On July 4, 1804, he landed here, and at once began practice. He gave clinics in the almshouse (1807), and was professor of midwifery in the College of Physicians and Surgeons, and professor of materia medica in Rutgers Medical School. He was also professor of chemistry. Dr. Francis says that “the stores of ancient and modern science were equally accessible to him, and he was ever ready to communicate.” When he died, “all felt that learning had lost a distinguished ornament, . . . the charities of life an ardent friend, and patriotism one who had sustained martyrdom in her glorious cause.”

Another man in the faculty with Dr. Mott, Dr. Macnevin, and Dr. Francis was Dr. David Hosack, “distinguished beyond all his competitors in the healing art” (1769-1835). Beginning with materia medica, he became professor in all the branches except anatomy and surgery. In 1804 he had to do with a tragedy which is a part of our history. When Alexander Hamilton was shot by Vice-President Burr on that early July morning at the Weehawken dueling ground, Hosack was waiting for him in a boat below the cliff. This was the untimely end of the great Hamilton, and the end of dueling in this country.

Dr. Hosack's favorite study was botany, and in 1801 he succeeded in establishing the State Botanical Garden upon twenty acres bounded by Forty-seventh and Fifty-first Streets, between Fifth and Sixth Avenues. This was for the “conservation of our indigenous botany, or as a repository of the most precious exotics.” It was a curious and valuable place in many ways, but not very useful, so the property was turned over to Columbia College. You all know how valuable the ground has proved to it. Dr. Hosack was one of the originators of the New York Historical Society, and twelve years its president.

In 1824, when Lafayette revisited America after half a century of absence, he was shown all possible honors, and Dr. Hosack, conducting him to the chair that once belonged to Louis XVI, “in a graceful speech tendered him his election as an honorary member of the Historical Society.”

His name is connected with most wise and great affairs of his day. It was he who established the library

of New York Hospital which has now been (1898) transferred to the Academy of Medicine.

"It was not infrequently remarked that Clinton, Hosack, and Hobart were a tripod on which our city stood."

Another botanical M. D. was James E. De Kay (1792-1851), an all-round naturalist. His travels took him to Turkey, where he became superintendent of the naval yards. He returned to Oyster Bay, near his intimate friend, the poet Bryant. Though he cared little for practice, he came here at once to help care for the cholera patients, and wrote chiefly for the New York press.

John W. Draper, M. D. (1811-1882), chemist and physiologist, was a many-sided man. After practising a few years in Virginia he came here, and with Mott and others founded the New York University Medical College. He did much in the early days for photography. It was he who first photographed from high-power microscope lenses. He wrote with equal ease upon chemistry, *Intellectual Development of Europe*, *The Future Policy of America*, and the *Conflict between Religion and Science*.

Contemporaneous with Dr. Draper, though older, was another M. D. who did not practise—Peter Irving (1771-1838), M. D., from Columbia. Peter was brother of Washington Irving, and helped the latter with the immortal *Knickerbocker's History of New York*. He found the pen mightier than the bistouri, and after traveling widely abroad led a literary life, being noted for his "classical acquisition and *belles-lettres* knowledge."

Medicine combined with art in the anatomical lectures given by Dr. T. G. King before the National Academy of Design. The academy originated with S. F. B. Morse, of telegraphic fame, who was its president for many years. He was a great painter, especially of portraits. One of Lafayette by him is still in the City Hall. Morse and King continued the anatomical lectures many years.

In January, 1831, chemists, physicians, and others began to agitate the subject of pure water. Dr. De Kay prepared a report including a quotation from Devoe in 1798, to wit: "The collect behind the tea-water pump is a shocking hole, where all impure things centre together and engender the worst of unwholesome productions." All this is now completely changed; the shocking hole has been filled up, and in or on its place stands the Criminal Court Building, where the New York Health Department resides and engenders hygienic laws and antitoxines instead of "unwholesome productions." The Croton water supply was brought to the city with a great celebration in 1842, having cost twelve million dollars.

In the medical history of New York no one took so great an interest as John W. Francis, M. D., LL. D. (1789-1861). In 1809 Dr. Francis was the first man

to receive the degree of M. D. from the College of Physicians and Surgeons. He later was professor of materia medica, of medical jurisprudence, and of obstetrics there. He was greatly interested in all the hospitals, asylums, and benevolent institutions of his time. He said "You might as well create a practical navigator by residence in a sylvan retreat as furnish a physician without hospital experience."

Dr. Francis was the medical friend of the leading actors from Cooke to Macready. Kean went with him to Vauxhall Garden (where Astor Library now is) and turned somersaults there. They then went to Bloomington, as Kean was anxious to see if our insane were like those in England. He nearly ended his own life on this trip. Dr. Francis wrote various medical papers, but is now best remembered by his *Old New York*, or *Reminiscences of Sixty Years*. Though a busy practitioner, he had time for the meetings of the famous "Bread and Cheese Club," where he met the naturalist Dr. De Kay and Charles King, later president of Columbia.

Dr. Kane, the Arctic explorer, was born in Philadelphia in 1820, and entered the navy as surgeon. He was a great traveler, and visited all parts of the world while on duty or during furloughs. During the Mexican War (1846) he was with the military staff. Being a naturalist as well as a sailor, he went with the first Grinnell Expedition from here in 1850. In 1853 he commanded the *Advance*, and first definitely determined the existence of an open polar sea. His expedition accomplished more than any preceding one, and brought him honor and fame. His health failed, and he sought relief in Havana, where he died in February, 1857.

Another man to whom we New Yorkers are especially indebted is Rufus H. Gilbert, M. D. (1832-1885), who invented the elevated railroad. He was a student of Willard Parker, and graduate of the College of Physicians and Surgeons. In 1862 he was surgeon to the Duryea Zouaves, and performed the first surgical operation under fire at Big Bethel. Later he was director of the army hospitals. After the war his health failed, and he became assistant superintendent of the Jersey Central Railroad. He was greatly interested in the overcrowding of the poor districts, and so labored to find a way of relief. The original elevated railroad, from Battery Place through Greenwich Street to Thirtieth Street, was begun in 1867. Dr. Gilbert at first held a large amount of the stock, but he lost most of it, and his death was really hastened by anxiety and disappointment.

In these days of interchanging war and peace we are reminded of Richard J. Gatling, M. D. (1818), who is still living in our city. His inventions so filled his mind that he never practised medicine. When a boy he perfected a cotton-seed sower and a wheat drill. (How he might have helped the gynecologist with cases of sterility!) In 1861 he invented the revolving gun

which was tried by General Butler and later adopted by the United States service. It is, as you know, virtually ten breech-loading rifle barrels together, and can now deliver twelve hundred shots a minute. Its efficiency may be learned by reference to the Manila battles of recent dates.

Of all medical men and patriots there is none whose history is so romantic or whose deeds are so daring and magnificent as those of Marcus Whitman. His name is inseparable from that rich territory

"Where rolls the Oregon, and bears no sound
Save his own dashings."

In 1836 he left this State with his young wife for a bridal tour of thirty-five hundred miles. When the party reached Fort Laramie the garrison tried to prevent his going beyond with his "old wagon." The great forests were then occupied only by Indians and traders of United States origin or belonging to the Hudson Bay Company. There this little band meant to go and did go. In 1842, six years late, Whitman was visiting a patient at Walla Walla and attended a dinner of traders and others where an express rider announced that a quantity of immigrants were two hundred or three hundred miles above, coming down there. An enthusiastic priest jumped up, shouting, "Hurrah for Oregon! America is too late!" Whitman grasped the situation, and left for home. In twenty-four hours he had started, in spite of all entreaties not to do so, to ride to Washington to see Webster before the Ashburton treaty should be signed and Oregon lost to the United States. It was a rich possession, of thirty-two times the size of Massachusetts, and Whitman's residence there six years showed him its value. The experiences of four months of winter spent in the saddle, pushing on constantly over mountain passes, through forests, swimming rivers frozen half over, at times eating dog meat and mule meat, and once being wholly lost—what history it is, and what an indomitable will the man had! Mr. Lovejoy and the guides were his companions, yet he may be said to have made the trip alone.

After five months' travel he reached Webster at Washington, and set aside all the arguments against the worthless and inaccessible land. When told that wagons never could be taken over the mountains, his sufficient reply was, "My wagon is there now." He returned on September 4, 1843, with two hundred wagons and nearly a thousand persons (eight hundred and seventy-five) and thirteen hundred head of cattle.

Daniel Webster said, "It is safe to assert that our country owes it to Dr. Whitman and his associate missionaries that all the territory west of the Rocky Mountains and south as far as the Columbia River is not now owned by England." The rides of Paul Revere and Sheridan were momentous, but Whitman outdistanced them and saved us six thousand miles of Pacific coast and inestimable wealth yet to be secured. Poor

Whitman and his family were massacred in November, 1847. Compare his journey with a trip by the Northern Pacific or Sunset Limited. Since his day our western horizon has been pushed seventy-five hundred miles farther.

I can not well refrain from reference to one eminent doctor now living and very active—Dr. Leonard Wood, now brigadier-general and military governor of Santiago. Governor Roosevelt, his long-time friend, counts him one of our most superior public men. He received his medical diploma from Harvard in 1882, and for a short time practised in Boston. His adventurous spirit led him into the army, and shortly we find him with General Miles fighting the Apaches. His great power of endurance, his kindly manner, and unusually sound judgment soon made him the natural leader of some of the detachments sent out. He soon won the medal of honor. It was the most natural thing in the world that he should command that unique regiment, the Rough Riders, and his evident executive ability and justice made him the natural selection as governor of the province. He is a man whom we may proudly claim as one of us, though he has grown out of medicine.

There is one doctor who belonged to all English-reading people—Oliver Wendell Holmes, M. D., LL. D. (1809–1894), the "autocrat," "professor," and "poet." A student of law, then of medicine; professor of anatomy and physiology for forty-four years in Dartmouth and Harvard; a poet from his college days to the end of his long life. The dry subject of anatomy he enlivened by comparing the sweat glands to a fairy's intestine, and the mesentery to shirt ruffles of a former generation. He wrote *Lectures on Homœopathy and Kindred Delusions*, and many other medical topics, yet found time to write fourteen volumes not medical.

Dr. Holmes was pre-eminently the poet for occasions

"When the tongue has grown loose
And the waistband grown tight."

He frequently came to New York (where else can a Boston man go?)—in 1853, to attend the meeting of the American Medical Association, and later the semi-centennial of the New England Society. When the new Fifth Avenue Theatre was opened, "they were something more perplexed for poets than for port and sherry," and Dr. Holmes was the poet guest. His most notable visit here was in 1883, when the New York medical profession honored itself in honoring him with a dinner at Delmonico's. Two hundred and fifty most eminent physicians and guests united in paying tribute to the genius, wit, and learning of the doctor-poet, who could

"... show with demonstrator's art
The complex chambers of the heart,
Or, armed with diviner skill,
To make it pulsate at his will."

Among the speakers were Dr. Barker, Dr. A. H. Smith, and Dr. T. G. Thomas, the Hon. William M.

Evarts, George William Curtis, Whitelaw Reid, and, best of all, the doctor himself in a poem.

This paper must have an end, and perhaps it had better be here. We have found that the knowledge of medicine adds to the efficiency of those possessing it; that it is compatible with many things else—law, preaching, literature, painting, poetry, natural history, exploration, astronomy, invention both in the arts of war and peace, and adds dignity, honor, and usefulness to a man in any profession.

SOME FURTHER OBSERVATIONS ON OBSTETRIC CASES.*

By JOHN H. BARRY, M.D.,
 PHYSICIAN TO ST. JOHN'S HOSPITAL, LONG ISLAND CITY.

EXACTLY three years ago the writer had the signal pleasure of reading before this society a report, published later in the *New York Medical Journal*, of two hundred and fifty maternity cases treated by him.

He then called attention to his extreme good fortune in having encountered a most unique and anomalous experience, and in having been favored by most satisfactory and flattering results. And in recording now the noteworthy points in slightly more than a hundred additional cases since that time he lays a humble claim to a continuance of said uniqueness, and acknowledges an obsequious gratefulness to Him who has visited a like good fortune upon his more recent efforts. For, although, in respect to a few conditions at least, his infant mortality may have been disappointing, yet the consciousness of diligent effort to succeed, tempered by the hope that years may bring increased success, has been a most comforting and consoling consideration.

I mean to touch to-day, gentlemen, with your kind permission, upon many most divergent obstetrical points, writing an essay upon none, but discussing, here briefly and there at more liberal scope, details of presentations, diagnosis, and manipulations which form, to

my mind, the elements of the successful conduct of a maternity case.

The intelligent observation and industry brought to the study of this ever-absorbing branch of the physician's art, the genius, tact, and acumen daily unearthed to a welcoming and receptive scientific world, make us of feeble attainments halt at a point far below where originality, invention, and discovery begin. So that I may be pardoned if I fail to startle with revelations of hitherto-unsolved problems, or illuminate with a calcium glow realms one would fain traverse even under the guidance of any of the bright lights of the obstetrical firmament. A summary of the afore-mentioned cases would show about the following:

Normal vertex:

Spontaneous and uncomplicated delivery.. 82

Forceps cases:

Normally engaging vertex..... 8

Occipito-posterior (rotation occurring)... 7

Occipito-posterior (rotation not occurring) 4

Knee presentation:

Occipito-posterior in after-coming head... 1

Transverse:

Cephalic version..... 1

Podalic version..... 1

Elbow presentation:

Shoulder, and prolapse of cord..... 1

Vertex, and prolapse of cord..... 2

Twins 2

Eclampsia 1

Pulmonary infarction complicating delivery. 1

Complications and sequelæ:

Malarial fever, very frequent.

Acute mania..... 1

Face rotating completely around in otherwise normal cases..... 2

Phlegmasia alba dolens..... 4

Adherent placenta..... 4

Adherent membranes 6

Noteworthy points:

As to diagnosis of faulty presentations.

As to shoulder extraction.

As to diagnosis of living child in transit.

As to false pains of labor.

As to seeming association of more or less adherent placenta with fairly good-sized children.

As to quinine by proxy for infants.

As to needlessness of worry about delayed labor when not begun upon rupture of membranes.

In the broad scope that this list might permit, one must necessarily confine himself in particular to a few of the conditions, making cursory remarks only of many of the points which it suggests. I have thought it well to select for the broadest discussion occipito-posterior cases, shoulder extraction, and malarial fever in the puerperium.

Now, as to occipito-posterior cases: Not without rea-

* Read before the Medical Society of the County of Queens, February 28, 1899.

son have these cases been portrayed to us as portentous and difficult. Those of you who have met with any of said cases have doubtless had them deeply ingrafted upon your memories. Mention has been made in the paper previously alluded to of two cases, in one of which rotation occurred, the diagnosis not having been made. The other was tedious, but occurred in a most vigorous woman, and nothing amiss or untoward was observed, even though the head was born with the face directly anterior.

The cases of vertex, oblique to the pelvis, with the occiput to the rear when grasped by the forceps, and rotation occurring when the head reached the perinaeum, being but a step removed from occipito-posterior, strictly so called, will be discussed side by side with the latter.

The first case in the present group was attended April 7, 1896. In this case, as in the rest of this classification, I quote *verbatim* from notes taken at the time. Occipito-posterior position; forceps. Rotation of the head complete when the head reached the perinaeum, carrying the forceps completely around with it. Eclampsia in the mother in her previous confinement; œdematous, nephritic condition of the mother in the present one. Moderate perineal laceration; repair; green-stick fracture of upper third of humerus occasioned in the manual extraction of the shoulders; union perfect; pressure paralysis of arm for four days.

CASE II. *Transverse Position of Vertex*.—November 7, 1896. Labor of ten hours' duration; forceps delivery; blade marking over brow; subsequent swelling of eye; slow shoulder delivery; several minutes taken up in resuscitating the child; adherent placenta; fifty minutes of intermittent effort over expression of placenta, one third of its bulk pointing out of the vulva; laceration of the right vaginal lip; healing by granulation. Placenta delivered by the hand carried to the fundus of the uterus. Beefsteak placenta; curettement, under ether, twenty hours after delivery. Attachment of placenta was very firm, evidently due to a placentitis, pain having been complained of for some time over the left side of the fundus of the uterus, where the placenta was most firm. Temperature was only once 101° F. (fifth day); very slight fever from discharge; nervous, quick pulse throughout puerperium. Evidences of air hunger and weakened circulation twenty-four hours after delivery. Inhalation of oxygen very efficient; given when pulse rate was 160. Phlegmasia alba dolens upon getting up.

CASE III.—March 22, 1897, called to assist Dr. Bumster. Diagnosis vague before chloroform anesthesia; face, inclining to a brow presentation, easily made out after anesthesia. Head, engaging in transverse diameter of pelvis, face to the right of the mother; membranes ruptured some hours. TempORIZED a short while; some advance made under natural pains; face points becoming lost; diagnosed occiput to rear when head had engaged somewhat. Forceps applied after an hour's wait; slipping of same. Some advance with the forceps when traction was made distinctly backward. Forceps unlocked and reapplied; the head was brought down on the perinaeum with face directly anterior. Chin easily brought out below pubes. No rotation of shoulders; most difficult extraction of the same; little or no expulsive pain. Supposed fracture of

base of skull of babe; died in three hours. Adherent placenta; seventy-five minutes taken up in its delivery. Uneventful recovery of the mother; no laceration.

CASE IV. *Occipito-posterior of After-coming Head of a Knee Presentation*.—March 26, 1897, assisted by Dr. Bumster. Left-knee and right-foot presentation. Membranes ruptured eight hours; no pains of consequence; feet brought down under slight chloroform anesthesia; waited considerable time for natural pains. Chloroform readministered and extraction begun; arms ascended about head; difficult delivery of same; occipito-posterior of vertex; rotation of the body, after some trouble and much caution, effected rotation of the head; very difficult extraction of the head; occiput rotated to the right, anterior; flexion was attempted by counter-pressure over the occiput and traction on the mouth and chin; child was stillborn. The placenta, adherent in a previous confinement, was easily delivered. Perhaps the smaller size of the child, it appearing to be two or three weeks premature, had something to do with this; douches in the lying-in period.

CASE V. *Right Occipito-posterior Position*.—August 30, 1897, called to assist Dr. Bumster. Difficult forceps; head rotating when low down; laceration of the perinaeum; repair; good recovery in mother; child born alive and vigorous.

CASE VI.—September 15, 1897, called to assist Dr. Bumster. Head engaged in the transverse diameter of the pelvis; fairly immovable; twelve hours in labor when forceps was easily applied. Considerable traction by colleague; less by the writer. Satisfactory evidence that child was living, and perhaps vigorous when the head rested on the perinaeum and forceps were removed. Face became very cyanotic (an evidence of its vitality). It was, perhaps, better judgment not to have expressed the head until involuntary pains were helped by voluntary ones, as the patient was rapidly becoming conscious; or perhaps there was too much delay in introducing fingers into the axilla and extracting the shoulders. Child was stillborn; bruised, ecchymosed spot slightly to the right of centre of the frontal bone corroborated the diagnosis of the position.

CASE VII.—November 12, 1897, called to assist Dr. Frey. Chloroform anesthesia; head grasped primarily almost antero-posteriorly, indicating a transverse position of the vertex. Scarification of nose and suboccipital region; slight abscess later in the latter region; rotation of the occiput on the pelvic floor; child born living; good recovery in mother; slight laceration and repair of perinaeum.

CASE VIII.—July 17, 1898, called to assist Dr. Bumster. Occipito-posterior position; head transverse at first; later, occiput to the left sacro-iliac synchondrosis; difficult forceps extraction, frequent unlocking of blades. Rotation of the blades and the head at the outlet; slight scar over occiput; upper lip swollen and slightly cut from forceps blade. Diagnosis correctly made and confirmed; child born living; no laceration; no reaction in mother.

CASE IX.—Called to assist Dr. McKeown. Seen by the writer with labor well advanced regarding dilatation of the cervix and firmness of pains. Head not engaged; thick, œdematous, strangled condition of the cervix, such as would be met with in a contracted pelvis. Dr. McKeown had experienced considerable difficulty in applying forceps, which, with the difficulty of handling the anæsthetic at the same time, became the occasion of my being sent for. It was fairly easy to recognize

that the occiput lay posteriorly, the very considerable difficulty of applying blades corroborating that point. After considerable traction, the infant was delivered with an expulsive shock. No rotation of head or blades occurred; completed as occipito-posterior direct, with considerable laceration of the perineum; repair of the same; a fairly large hematoma of the right side of babe's neck, slightly posterior to the ear; some excoriation of the same. A distinct flattening or indentation (an eighth of an inch) of infant's skull over the left anterior angle of the parietal bone. Paralysis of left side of the mouth and ptosis of left eyelid for an hour. Weak, cerebral cry of babe; incision of scalp and elevation of skull discussed; temporized; improvement in a few hours from intracranial pressure (e.g., as caused by crying, etc.). Flattening less distinct by the next day; child more vigorous; saw it again in a week; it was improved in every respect; advised by Dr. McKeown that the child progressed exceedingly well. Position: Occiput to the left sacro-iliac synchondrosis, chin to the right ileopectineal eminence; lateral flexion of the neck with its convexity to the right of mother. Considering everything, version would have been a much preferable procedure. Forceps delivery, I can not help but think, was fraught with much possibility of at least remote, if not immediate, danger; such a case would be one the like of which is spoken of as being a cerebral case, or one likely to develop meningitis later on in life. Deterrent points from performing version were the drained membranes and the pinched condition of the cervix, arguing, it appeared, for lack of room for skillful and, if need be, dexterous manipulation.

CASE X.—September 17, 1898. Faulty labor, due, in great measure, to the nervous apprehension of the mother. Inertia uteri; chloroform; forceps; easy extraction; good rotation; protracted anesthesia; slight excoriation over right eye of babe, followed by swelling of the same; very transitory; no untoward results; mother made a perfectly good recovery.

CASE XI.—October 19, 1898. Caput succedaneum to the right of the occiput, forceps blade lying over the left eye, temporarily marking and swelling the same. The head was oblique to the pelvis; a deep perineal rent; slight adherence of the placenta; a most difficult and slow extraction of the shoulders; babe was quite cyanotic; it was vigorous, however, and quickly restored.

CASE XII.—January 10, 1899, assisted by Dr. Bumster. Called when labor was slightly advanced; found prolapse of cord, complicating a vertex presentation. Only a few inches of cord had prolapsed, and one was able without exceeding difficulty, to carry it up above and behind the head during the pains until slight advance of head in the pelvis shut it off and away from the examining finger. Progress being very slow (all the more particularly since the mother had previously had several rapid, easy deliveries), anesthesia and forceps were decided upon, not before, however, vertex had well settled into inferior strait. Rotation of head and blades occurred when the former reached perineal floor. External rotation of the head (face to the pubes) corroborated position and brought shoulders into the transverse diameter of the pelvis. Cord was felt for and found encircling the neck; it was passed over head. Anesthesia had been suspended in the hope that Nature might help to initiate where art often but poorly stimulates the mechanism of shoulder delivery. Mother's efforts proven practically unavailing, we were confronted with one of the most difficult manual extractions of shoulder in our ex-

perience. A conservative estimate agreed in by both of us would set the shoulder extraction at fifteen minutes of unremitting effort; all hope of saving the child had long ago been abandoned when the child was born. Vigorous efforts at resuscitation were soon rewarded by an infant's gasp, replaced later by several hours of feeble moaning, the latter giving way in turn to the lusty cry of a vigorous babe; the child weighed twelve pounds and a half. Repaired perineum; mother's recovery uneventful.

I am alive to the likelihood of a harsh criticism upon the conduct of these cases; I am sensible of the disposition you all feel to have possibly done otherwise; I am aware that I might be given credit for better judgment and skill in having done version in many of these cases; I am satisfied that it is probably the teaching of the best minds; and yet, for all that, possibly because of a good fortune attending my efforts, I am almost ready to stand on this record. I have felt that, now for one reason and again for another, insurmountable contraindications to version presented themselves. I may be considered heretical in saying so, but I will express an emphatic doubt as to whether, after all, better results would have attended the child and the mother in the pursuit of different methods. Take, for instance, a case presenting occipito-posteriorly and perform a version: Have we any assurance, after such tax on a child's vitality (and it is in certain cases at least a tax), that, despite the trouble one commonly meets with in the management of the shoulders, an occipito-posterior position of the after-coming head might not be encountered? You will recall, perhaps, that one of these cases presented by the breech originally, and, if the breech extraction were not faulty, how comes it that we had an insurmountable difficulty to successful delivery in the management of the shoulders and head? For one should remember that in an occipito-posterior the abdomen of the child lies in apposition to the mother's abdomen, and that version must be accompanied by such a rotation of the child's body as to engage the after-coming head in an occipito-anterior position in the pelvis. Can this always be trusted to an easy accomplishment, and is it not an element in the advisability or otherwise of what to do under certain given conditions? And, again, for instance, in a shoulder case with prolapse of the cord, to which I shall have no more time than this to refer, though a version was rapidly and dexterously accomplished by Dr. Bumster, it is only fair to say, in a supposedly weakly child, from the history of the case, with the same failure of the child's head to rotate there was a grewsome termination of an otherwise possibly fortunate case.

As to diagnosis of faulty vertex positions, I shall mention just a few which occur from a mental rehearsal of practical incidents and not promulgated as a studied research of the subject:

1. Fontanelle and suture, digital examination.
2. Show progress in the presence of good labor pains.

3. Asymmetrical engagement of the head in relation to the sides of the pelvis—*e. g.*, an evidence that one blade of the forceps might be much more easily introduced than the other.

4. Failure of the forceps to lock.

5. Tendency of the forceps to slip.

6. Rotation of the blades.

7. Corroborative sign (position of the caput succedaneum).

8. Corroborative sign (face markings caused by the forceps).

As to the diagnosis of a living child in transit:

1. Integrity and seeming fullness of the skull cavity as compared with much overlapping and laxity of the same.

2. Cyanosis of the face.

3. Crying of the babe.

4. Fœtal heart.

In breech cases: 1. Response to peripheral stimuli.

2. Seat of the fetal heart sound higher.

In prolapse of the cord: Pulsation.

As to manœuvres in shoulder extraction:

1. Disengage an encircling cord, if existing.

2. Caution as to fracturing a limb.

3. Overcome or reverse an extreme rotation, that the shoulders may be brought antero-posteriorly.

4. Sometimes advisable to try the anterior shoulder first.

5. Correctly gauge the chloroform anæsthesia so as to gain the help of voluntary pains.

6. Use of the fillet or blunt hook.

7. Sweep the arm in the plane of a natural movement.

8. Judge the necessity of hurry.

As to puerperal malaria:

It is altogether possible that obstetricians of note have not found it either profitable or mandatory to reside in malarial districts, and this may be a reason why malarial fever as a complication of the puerperal state has not been enlarged upon in treatises on obstetrics. While far from claiming a rating with authors, permit me to say that I feel I have recognized it as a very common complication—so common, in fact, that I scarcely ever fail to give quinine in the lying-in period where a history of malaria, recent or remote, can be elicited. Its administration serves the double purpose of insuring a quiet, uneventful puerperium (other conditions being equal) and granting one a freedom from the recognition and observance of chills, fever, and associated conditions which at other times excite no apprehension, but, occurring in the convalescence from childbirth, may be fraught with direful forebodings, and instigate a fear that something might be amiss in the genital tract. And in this connection I beg leave to quote from notes in at least two remarkable cases:

CASE I.—Mother suffered from a severe chill about an hour before delivery; child, though born in normal

labor, appeared listless, dull, and irresponsive to stimuli. The inference seemed clear that the child was suffering from malarial fever, developed in utero. The mother was immediately treated with quinine. Good results to mother and child, periodicity of symptoms being noted. The mother had had no evidence of malarial intoxication since her previous confinement, two years prior to the present one.

CASE II.—After the third day of infant life, the child, previously noisy enough, became very dull and inordinately sleepy, awaking only at very infrequent intervals to nurse. The mother had been encouraged from the outset to take quinine, but she failed to do so. The stupor and sleepiness increasing during a period of four to five days, the nursing was suspended; quinine was given the mother, and oleate of quinine used on the child; good and prompt results.

I long ago reached the limit of a paper such as this, and I shall abruptly close with an expression of my sincere thanks for your kind attention.

THE OCCURRENCE OF THE STREPTOCOCCUS SCARLATINÆ (SO CALLED) IN CULTURES FROM THE THROATS IN CASES OF SCARLET FEVER.

BY JOHN S. BILLINGS, JR., M.D.,

ASSISTANT BACTERIOLOGIST, DEPARTMENT OF HEALTH, NEW YORK CITY;
INSTRUCTOR IN CLINICAL MICROSCOPY
IN NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL SCHOOL.

IN 1887 Klein isolated from the blood of cases of scarlet fever a streptococcus presenting certain cultural peculiarities, which streptococcus he believed to be causally related to the disease. In bouillon it formed a cloudy, flocculent white sediment at the bottom of the culture tube, leaving the remainder of the bouillon perfectly clear and limpid; and it caused rapid coagulation of milk. This organism was also isolated from the ulcerations on the udders of cows whose milk had been proved to have disseminated scarlet fever.

In 1890 Kurth* described a streptococcus similar to the one described by Klein, which he found in the throats of scarlet-fever patients, and which he called the *Streptococcus conglomeratus*. In bouillon cultures it showed a cloudy deposit in the otherwise clear serum. Stained microscopical specimens of this deposit showed it to be made up of a conglomerate, closely woven mass of streptococci. He also states that this organism, in contradistinction to all other known streptococci, was extremely pathogenic to white mice.

Klein† confirms these observations of Kurth's in a report on eleven cases of scarlet fever, from which he isolated the above-described streptococcus. He calls attention again to its power of coagulating milk, and

* Kaiserl. Gesundheitsamt, announced at Tenth International Congress in Berlin, 1890.

† Twenty-seventh Annual Report of the Local Government Board, London, Supplement, 1898, p. 326.

Scarlet Fever.

DATE.	No.	How made.	Result of incubation.	Sediment.	Microscopical examination.
January 19th.....	1	Peptone-bouillon culture from serum tube.	General cloudiness of bouillon in twenty-four hours.	Slight amorphous.	Staphylococci and large bacilli.
January 19th.....	2	Peptone-bouillon culture from serum tube.	As above.	None.	Staphylococci. Few streptococci.
January 21st.....	3	Peptone-bouillon culture from serum tube.	As above.	None.	Staphylococci.
January 21st.....	4	Peptone-bouillon culture from serum tube.	As above.	As in No. 1.	Staphylococci and bacilli.
January 25th.....	5	Peptone-bouillon culture from Petri dish. Round, translucent colonies. Made at W. P. Hoop; edges sharp; elevated.	Cloudiness at end of twenty-four hours in two tubes. Slight filmy deposit.	Contact smear showed few short chains. Smear from bouillon showed moderate number of streptococci.
January 25th.....	6	Made as in No. 5. Colonies as in No. 5. Also irregular colonies shading off into media.	Cloudiness at end of twenty-four hours in four tubes from both kinds of colonies.	Amorphous deposit.	Smear from diffuse colonies showed diptheria bacilli. From tube, only staphylococci.
January 25th.....	7	Made as in No. 5. Colonies as in No. 5.	Cloudiness at end of twenty-four hours in three tubes. Further incubation increased cloudiness.	Filmy deposit.	Smear from filmy deposit showed only staphylococci.
January 25th.....	8	Made as in No. 5. Colonies as in No. 5.	Slight cloudiness at end of twenty-four hours, increasing at end of forty-eight hours.	Flocculent deposit.	Smear from plate showed moderate number of staphylococci. Smear from tube showed many large streptococci.
January 27th.....	9	Made as in No. 5. Colonies as in No. 5.	Marked cloudiness at end of twenty-four hours.	Film above and at bottom.	Smear from film showed many staphylococci; no chains.
January 27th.....	10	Made as in No. 5. Large, translucent, round, elevated colonies; whitish.	Slight but distinct cloudiness at end of twenty-four hours. No change at end of forty-eight hours.	Granular sediment.	Smear from sediment: No chains; cocci.
January 27th.....	11	Made as in No. 5. Small, yellowish, opaque colonies.	Bouillon absolutely clear and limpid at end of twenty-four hours; also forty-eight hours.	Flocculent white deposit.	Smear from deposit: Composed entirely of staphylococci; not a single chain observed.
January 27th.....	12	Made as in No. 5. Colonies as in No. 10.	Slight cloudiness at end of twenty-four hours; increased at the end of forty-eight hours.	None.	Smear from plate showed pure culture of streptococci.
January 27th.....	13	Made as in No. 5. Colonies as in No. 11.	Marked cloudiness at end of twenty-four hours, diminishing markedly on further incubation.	None.	Almost a pure culture of streptococci (from tube).
January 27th.....	14	Made as in No. 5. Colonies as in No. 5.	Slight cloudiness in twenty-four hours, increasing in forty-eight.	Filmy deposit.	Small bacilli, cocci, and a few short chains (from tube).
November 8th.....	15	Frank Stevens, ill twenty-four days; temperature, 100.2°. W. P. H. Culture made by Dr. Park on November 6th. Incubated from 6 p. m., November 6th, to 9 a. m., November 8th. Oval, semitranslucent, sharply defined colonies, mostly whitish. A few yellowish, but not golden.	Three bouillon cultures made 9 a. m., November 8th: (a) Cloudy; granular deposit..... (b) Cloudy in twenty-four hours..... (c) Cloudy in twenty-four hours.....	Granular. Granular. Granular.	Staphylococci and bacilli. Streptococci and staphylococci. Staphylococci.
November 8th.....	16	Mary Fav, six days ill; temperature, 100.2°. Culture made as No. 15. Large and small circular, whitish colonies. Also some golden yellow colonies. Medium sized colonies have spot in centre and thin out to edge; also a few very large colonies. Three days' incubation failed to show the brownish spotted colonies described.	Five bouillon cultures, 9 a. m., November 8th: (a) Very cloudy (aureus), twenty-four hours..... (b) Cloudy, twenty-four hours..... (c) Cloudy, twenty-four hours..... (d) Clear, limpid, twenty-four hours..... (e) Clear, limpid, twenty-four hours.....	None. White, flocculent. None. White, flocculent. White, flocculent.	Staphylococci. Streptococci and bacilli. Large bacilli. Streptococci, short and long chains, milk coagulated. Streptococci, short and long chains, milk coagulated.
November 8th.....	17	Elsie Stevens, four days sick; temperature, 103.2°. Culture made as No. 15. Only four round, whitish colonies, opaque, no spot in centre.	Three bouillon cultures made 9 a. m., November 8th: 1. No growth, forty-eight hours..... 2. Cloudy, twenty-four hours..... 3. Cloudy, twenty-four hours..... Granular. None.	None. Staphylococci and streptococci.

also to the characteristic brownish spotted appearance of the colonies growing on agar-agar.

Cultures from the throats in seventeen cases of scarlet fever have been examined at the diagnosis laboratory of New York City Department of Health. Of these, four were cultures on serum-agar tubes made by inspectors of the bureau of contagious diseases, stated that the cases were undoubtedly scarlet fever. The remaining thirteen cases were seen at the Willard Parker Hospital, where they had been admitted as scarlet fever and the diagnosis confirmed. The cultures were made by Dr. William H. Park, in accordance with the directions given by Klein in his second article.

In every case at least three, and sometimes more, bouillon cultures were made from the agar plates, such colonies being selected as resembled those described by Klein in his second article. These bouillon cultures were incubated from twenty-four to forty-eight hours. Smears were made from the deposits in the tubes, and in one or two instances direct contact smears were made from the plates. In about fifty per cent. of the cultures colonies were observed which presented a spotted appearance as described by Klein. As shown by the preceding table, the results were practically negative. In only one instance was a streptococcus corresponding in cultural characteristics to the *Streptococcus scarlatinae* isolated (see table, No. 16). So that while the so-called *Streptococcus scarlatinae* or *conglomeratus* does occur in the throats in some cases of scarlet fever, it is either not constantly present or, in the great majority of cases, is isolated with great difficulty. The question as to whether its presence is diagnostic of scarlet fever has not been considered here, but it is very doubtful. Its absence in cultures from the throat in a case of suspected scarlet fever in no way negatives the diagnosis. It is possible that the wide variation between these observations and those of Klein and Kurth may be due to differences in the disease itself as occurring in this country and abroad.

32 EAST FIFTY-THIRD STREET.

A CASE OF ACUTE TRANSITORY MANIA OCCURRING IN A SYPHILITIC MORE THAN THREE YEARS AFTER APPARENT CURE OF THE SYPHILIS.

By CHARLES O'DONOVAN, M.D.,

PROFESSOR OF DISEASES OF CHILDREN
IN THE WOMAN'S MEDICAL COLLEGE OF BALTIMORE.

On January 5, 1899, I saw P. D., white, aged twenty-five years, of Irish birth; married. He worked as a track hand on the railroad and had been always well and strong until this illness. About a week before I saw him, while walking along the street in company with several other men, and in apparently perfect health, he fell, suddenly and without warning, in a fit, which was evidently epileptoid, from the graphic description of several of the men who were with him. He

lay unconscious for about ten minutes, and was then able to walk to his home, in a dazed condition, with the assistance of a man on either side of him. He had no recollection of the attack beyond what he learned from hearsay, and could not understand why his friends made such a fuss about it. He was not a heavy drinker, although he would occasionally take a few glasses of beer, and he had had a little before the fit came on. He had been seen by a competent physician, who had treated it as the result of more drink than was acknowledged. He had no more attacks until the night before I saw him, when he had one, which caused his wife great alarm, and led her to arouse his brother, who lived near. He had had several friends at his house before going to bed and there had been some drinking, but he had taken very little, according to the testimony of those who had been present. When I saw him he seemed perfectly well, although his family insisted that he was very different from his usual self; but, being rather ignorant people, they could not exactly define the difference. His lungs and heart were normal, his pulse rate was not hurried, and the arterial tension was low. His stomach, bowels, and kidneys appeared to perform their functions correctly. His speech was perfect, his eyes looked natural, he complained of nothing except considerable loss of muscular power, a weakness that he was not accustomed to, but which was readily accounted for by the violence of the fit. He was perfectly sane and rational on every point, but he had no recollection of anything that had happened in the night. There was no elevation of temperature when I saw him. He was given a solution of bromide of sodium, with compound tincture of cinchona, to be taken three times a day, each dose containing twenty grains of the bromide. Everything went well until the early hours of January 10th, when, at about three o'clock, he had another severe attack, which lasted several hours, rather as a succession of epileptoid convulsions than as a continuous seizure. He had been perfectly well the night before, and no cause could be assigned for the seizure. He had taken the medicine regularly; he had eaten and slept well; he had had no headache or other symptom that could lead one to anticipate a return of the trouble. By 10 A. M. he was entirely over the attack, but remained quite weak, equally so on both sides, and had a heavy, dazed appearance about the eyes, although nothing in the eyes denoted any change from normal. He was rather angry that any extra notice should be taken of him than worried about his condition. His bowels and kidneys were acting well. The urine was acid, 1.026 specific gravity, and contained neither sugar nor albumin. He answered all questions correctly, but otherwise was moody and inclined to be morose. Several times during the day he had loss of consciousness for a minute or more, sitting or lying with eyes open but staring in a fixed direction, without any convulsive movement whatever. His appetite was unchanged, and all other functions appeared to be normal. During the following night he was again much worse, becoming delirious and very excited without any appearance of fever, as far as his family could judge. Though milder during the next day, he was evidently worse, both in mind and body. Further questioning showed that he had served for several years in the British army in India, from which he had returned about a year previously. There being nothing else evident to account for his anomalous condition, he was suspected of syphilis on general principles, although his answers to questions on the subject were very vague and contradic-

tory, so he was ordered large doses of iodide of potassium, beginning with ten grains three times a day, to be increased five grains each day, and mercurial inunction with twenty grains of blue ointment was to be given every second night. Before any effect could be expected from this treatment he grew much worse, becoming more and more wildly delirious, so that he had to be restrained forcibly, and was finally tied in bed to keep him from jumping out of the window, or otherwise injuring himself. He had no more epileptoid attacks, but his mind was completely wrecked, with no lucid intervals, and only short periods of sleep, without succeeding benefit. Removal to an asylum was urged unsuccessfully until the morning of the 15th, his family consenting only when it was evident that he was entirely beyond their control. After the first week in the asylum he began to improve, and rapidly regained consciousness, so that he was returned to his home at the end of a month. He was perfectly himself again, but still quite weak muscularly, as was to have been expected, and he had lost about twenty pounds in weight. Of his illness he could recall nothing until he regained consciousness during his second week in the asylum. Being asked after his return home about his life in the army in India, he admitted having had a hard chancre some three or four years previously, for which he was kept under treatment for more than a year at varying intervals. His description made it perfectly evident that he had had syphilis at that time and confirmed the tentative diagnosis made from the symptoms and strengthened by the result of the treatment. The man is still (March 15th) under observation and shows no deviation from ordinary health. His treatment now consists of a mercurial inunction twice a week with about thirty grains of blue ointment.

Probably the most interesting feature in the case related is the suddenness with which an apparently healthy man was completely overwhelmed by the syphilitic explosion. So far as I could discover, there existed no exciting cause whatever to account for the attack. He had had his primary sore about four years previously, for which he had had thorough and systematic treatment from physicians presumably capable. He had had no further manifestations of any kind, and naturally considered himself perfectly well. He attended to his work, which was quite heavy, without difficulty. He was married to a wife who showed no signs of infection. Though his nervous system appeared easily excitable, yet it was no more than one usually expects to find in any young Irishman of his age. The diagnosis lay between true epilepsy and syphilis of the central nervous system, the nocturnal occurrence of the paroxysms favoring either view; but the rapidity with which he went from bad to worse, and the development of maniacal symptoms so promptly, in spite of large doses of bromide, favored the diagnosis of syphilis. The discovery of his former life in the Indian army added to this probability, but the man's answers on the point of primary infection were most unsatisfactory at the time of his illness, although perfectly explicit after his return from the asylum. He had no disfiguring marks or cicatrices on any part of his body to aid in

diagnosis, nor was his hair in any way lessened. The mania was extremely violent, coupled with wild hallucinations, and was always worse at night. During the day his state was rather that of dementia, with constant suspicious watchfulness, as if fearing some injury from the members of his family. His improvement after removal to the asylum was rapid and continuous, but whether from the change of surroundings and better nursing, or from the antisymphilitic treatment, I am not prepared to say. How long it may be before he has further manifestations, and in what form they will appear, are interesting questions to be answered later.

DIPHTHERIA: THE SERUM TREATMENT IN GENERAL PRACTICE.*

By PALMER HEATH LYON, M.D.

THERE have appeared from time to time various articles which, if they do not altogether condemn, disparage the use of antitoxine in the treatment of true diphtheria.

The writer has been fortunate enough to see a number of cases in which he has felt positive that had not antitoxine been used nothing could have saved the patients. These patients received the serum and all recovered. Upon such evidence as this I have ventured to present a few arguments and observations which, while not new, seem to have a definite bearing upon the subject.

In the first place, I wish it to be distinctly understood that I am in thorough accord with those who maintain that the curative value is greatly diminished if the treatment is not begun in the first three days. After that it is almost useless to undertake to administer the serum—the time has passed. However, it is my firm belief that up to that time, in every case in which it is not absolutely contraindicated, it should be tried. While it will probably be of no avail, it should be tried even after that period is past, and it should not be done in a hasty or cursory manner, when other means have been fairly tried and failure has resulted. The general consideration of this subject naturally divides itself into three main channels: *When, where, and how* to administer the antitoxine.

Along the first of these groups our introductory remarks have carried us, and we will pass on, simply remarking that the earlier the remedy is used the better the results. The first day is, therefore, the best time, but very excellent results have been obtained in cases in which the inoculation did not take place until the second or third day.

The second division admits of little discussion. It is only natural that a site of operation should be selected

* Read before the Washington Health Medical Society, March 30, 1899.

that will provide ready absorption, inasmuch as on this depends much of the success of the treatment. For this reason there are two portions of the body admirably adapted. They are the surface of the abdomen in the lumbar region (either left or right; personally I prefer the left), or the external surface of the thigh. Of these, the former is, when practicable, the better. In the case of very small children, however, the latter mode presents fewer obstacles; therefore it is advocated when the other and favorite method can not be adopted.

Since this paper was started there have appeared several articles by distinguished writers upon the subject of oral administration of antitoxine. A serum may be produced in the future which will be suited to such a method, but certain it is that at the present day the hypodermic method is the one for which the various serums are prepared, and, until we have some better reason to discard it than we have at present, it is the one for us to retain. We have reduced the necessary quantity to a minimum by increasing the potential of the serum. Were we to use it *per os*, a much larger quantity would certainly be required.

But this in passing.

The next channel along which we direct our investigation is that of how to administer the antitoxine, and this I propose to divide into three portions—viz.: 1. The method of administration. 2. The amount to use. 3. General considerations. We will proceed in the order mentioned.

1. *Method*.—The very first consideration is invariably absolute asepsis. Instruments, receptacles, dressings—in fact, everything used—must be absolutely sterile. The skin of the patient must be washed with some efficient disinfecting solution. For this purpose I prefer a solution of lysol of a strength of four per cent. After this in several cases I found it advisable to produce local anaesthesia by means of either the ether or ethyl chloride spray. It is conjectural, however, whether this is really advisable with small children, as the cold and discomfort of such a procedure, to my mind, are greater than when the needle is carefully and quickly introduced. Still, in adults and older children it is often of much use.

With regard to the instrument or means of inoculation, any good antitoxine syringe will answer. There are many now on the market, all of which have their good points. I must speak here of a modification which might well be omitted. This is the use of a rubber tube between the syringe and the needle. After trying both with and without this, I have discarded it. It is a relic of the old rubber bulb syringe. The operation is rendered much easier by using the needle fast to the barrel. It is less painful to the patient, and the physician completes the inoculation without further difficulty. If an antitoxine syringe is not at hand, a large hypodermic one will answer, if a serum of a high potential is used.

If possible, the serum should be taken directly from

the containing flask, thus avoiding the risk of contamination. If, however, it becomes necessary to transfer the serum, great care must be taken that the new receptacle is sterile.

The operation complete, a sterile compress should be held on the puncture for a few seconds and then colloidion applied. It is not advisable to employ massage, as absorption takes place rapidly in these regions. The patient should be kept quiet for a short time immediately after the operation is completed.

Individuals who have been exposed may be immunized in the same manner, a smaller dose of the serum being used.

Before proceeding to a consideration of the subject of amount to be used, I wish most strongly to advocate the immunization of every person who may have run even any risk of infection. The cases I shall quote in a few minutes will emphasize this point, but it is my firm belief that with such precautionary measures our present low death-rate may be greatly decreased.

2. *Amount*.—The New York board of health has determined that the average curative dose is fifteen hundred units (Behring's). I have found that in the majority of cases this held good, but it is unwise to try to set any one fixed rule to cover all cases.

If (ten to twelve hours having elapsed since the original dose) there is not a decided improvement, a second dose of from two thousand to twenty-five hundred units should be given. It may even become necessary to give a third one of from three thousand to four thousand units. It is seldom that a third dose is needed when the treatment is begun on the first or second day of the disease. When treatment is delayed, however, it is sometimes necessary to give a third or even a fourth dose.

For immunization a dose of from five hundred to a thousand units is all that is necessary. The dose here is proportionate to the individual's age and strength, also to the general physical condition. I would remark that I have never seen a patient, properly immunized with these amounts, become infected. It is unfortunate, however, that this immunity is not lasting, but passes away after a period of from five to eight weeks.

3. *General Considerations and Deductions*.—Before considering this topic, I desire to refer to several cases which will serve the better to illustrate the foregoing.

CASE I.—S. C., a woman, aged twenty years. On December 13, 1898, she complained of a slight sore throat. She had been suffering from a heavy cold, but there were no symptoms pointing to diphtheria. On the next day, by means of the electric diagnostic appliance, I was enabled to get a view of the throat, which resulted in making a culture that, on the following day, showed the presence of *Bacillus diphtheriae*. The patient refused treatment by antitoxine, and, as isolation of the case was impossible, she was removed on the 16th to the Willard Parker Hospital, where she received twenty-five hundred units and made a good recovery.

In the family which she served as a domestic there

were three adults and two small children. Each of these persons received a thousand units of board-of-health antitoxine, and, although they had been constantly exposed, not one was afterward infected.

CASE II.—R. R., aged three years, and A. R., aged five years. These two children, together with others, were a most interesting group of cases which I saw through the courtesy of Dr. L. A. Rodenstein. R. was undoubtedly suffering from diphtheria. A., while showing no throat symptoms, still seemed suspicious. The sick one was given fifteen hundred units, and the others a thousand each. R. was sitting up in bed in four days, and there was no further complaint from the others. A. was perfectly well the next time I saw him.

CASE III.—Mrs. R., mother of the two children mentioned above, refused inoculation when she began to nurse her son. Three days after she was attacked by the disease in a very violent form. She received two thousand units, and twelve hours later three thousand more. In three days she was much better, and in a week she sat up for a short time.

CASE IV.—A. T., a boy, aged eleven years. A very severe case. On March 1st he awoke with a sore throat. When I saw him that afternoon the membrane covered both tonsils and the posterior pharyngeal wall. It was evidently the third day of the disease. I at once gave the child fifteen hundred units, and isolated him with his mother, to whom I gave a thousand units. He rallied slightly with this, but his temperature remained high (104.5° F.). In the morning I deemed a second dose necessary, so I gave him two thousand units. A slight drop in the temperature occurred, but it rose again during the next day, and at midnight it reached 105° F. His condition was very poor, and I felt but little hope. A third dose of three thousand units was administered, and in two hours the temperature began to fall. Before the change took place Dr. Rodenstein was called in consultation, and we agreed that the case was almost hopeless. The depression was extreme, and constant stimulation was resorted to in the hope of tiding over the crisis and giving the last dose of antitoxine a chance to work. As stated, the temperature fell, and in forty-eight hours had reached almost normal. The remainder of the recovery was ordinary. We were convinced, however, that the child had practically been snatched from the jaws of death, and to antitoxine we give all credit for the recovery.

CASE V.—E. T., aged thirty-seven years, the father of the foregoing patient, was obliged to attend to some trifling duty in the sick-room, and in three days he showed the disease. He was at once isolated and given fifteen hundred units. As he had been constantly with the rest of his family, consisting of four children, they were all immunized, with the result that none contracted the disease. He himself needed but the one inoculation, and made a speedy recovery.

Other cases might be cited, but I feel sure that the foregoing are sufficient to illustrate the matters referred to, and from which I feel that the following conclusions may justly be drawn:

1. Antitoxine, to be efficacious, should be administered early, the first three days being the reasonable time to expect good results.

2. The greater the time which elapses before the first dose, the poorer the patient's chance of recovery.

3. When immunized persons and those not so treated

are exposed to the same chances of contagion, the immunized escape, and those not so treated "take" the disease. We may, therefore, conclude that all exposed individuals should be at once immunized.

4. As severe cases which, ordinarily treated, terminate fatally, yield readily to this treatment, it is certainly to be regarded as good routine treatment, and, as the early treatment is the secret of success, the serum should be employed in all cases in which diphtheria is even suspected, even before the bacteriological diagnosis is complete, it being perfectly harmless if properly administered. By this I mean that the serum should be of standard preparation and not over six months old, and that perfect asepsis is the rule.

5. The only unpleasant effect is that sometimes a slight urticaria is observed about the site of inoculation (occasionally becoming general). This gradually passes away in the course of a few days, and is of trivial importance.

In conclusion, let me call attention to the fact that while the disease is usually quickly terminated by this most valuable remedy, unfortunately after-effects may follow, as is so often the case with other and far less successful treatments. I am glad to say that in the cases cited such has not been the history.

ANTINOSINE IN THE TREATMENT OF ENURESIS, CYSTITIS, AND URETHRITIS.

By R. E. AMYX, M.D.

ST. LOUIS,
SENIOR ASSISTANT PHYSICIAN TO THE ST. LOUIS CITY HOSPITAL.

In presenting the following cases, I desire to place before the medical profession a full and detailed account of the treatment which was employed. Not that I believe it to be a treatment which will in every case give results superior to many of the other known remedies used in the treatment of cystitis and enuresis, but because of its value in the cases I have to present to you, and of its good effects in cases which did not respond to other well-known remedies. The use of antinosine was purely experimental in the cases selected, but the good result obtained in the few cases in which it was used will give it a place among the best-known agents employed in cystitis and enuresis.

The following are the cases that I present:

CASE I.—Frank E., aged twenty-eight; native of Germany; occupation, laborer. Habits: Smokes tobacco moderately, drinks whiskey and beer to excess, uses no narcotics, indulges excessively in venery.

Family History.—Mother died of typhoid fever; one sister died of some affection of the lungs, the nature of which was unknown to the patient; other members of the family are alive and well. No facts history in the family.

Previous History.—Does not recall what diseases he had during childhood, except such of the disorders of the digestive, respiratory, circulatory, or nervous

system; had malaria several times, gonorrhœa several times, syphilis seven years ago, but denies having had secondaries.

Present History.—Patient entered the hospital intoxicated, having been drunk for several weeks. After having recovered from the effects of his indulgence in whisky, he complained of pain during urination and of frequent micturition, having to pass his urine from ten to fifteen times during the twenty-four hours; at times it was almost impossible for him to pass his urine, while at others he was unable to hold it. This latter condition was due to the existence of an old urethritis which had troubled him for the past three years. The patient states that he had been troubled several times with enuresis. Urinalysis: This showed the urine to be very light straw color, alkaline in reaction, ammoniacal odor; specific gravity, 1.024; slight trace of albumin, pus cells, and triple phosphates present; no sugar, bile, acetone, or indican present; no cast was found. After the patient had been in the hospital two weeks his enuresis became very annoying, owing to his urine passing involuntarily during his sleep, while the existing cystitis which he had gave no signs of improvement. During this time patient's bladder was irrigated with a one-fourth-per-cent. nitrate-of-silver solution without any marked improvement. In the meantime a No. 30 sound (cold) was passed every day in order to relieve the existing enuresis; this latter procedure had to be dispensed with, as it aggravated the cystitis. In addition to the local treatment, strychnine, belladonna, iron, and salol were administered internally. At the end of three weeks it was deemed necessary to seek some other local treatment than the nitrate-of-silver solution, and a 1-to-4,000 permanganate-of-potassium solution was employed with some effect on the cystitis. The enuresis, however, continued without any apparent relief. Having exhausted the best-known remedies for these conditions without any marked improvement, a two-per-cent. solution of antinosine was employed in order to diminish the amount of pus present in the bladder. (The antinosine solution had been used externally for cleansing several wounds in which there had been a large amount of pus. In these instances pus had disappeared under its administration, so it was deemed advisable to try it in this instance for the same purpose.) The patient received an irrigation of this solution daily for a period of two weeks. During the first week there was no manifest improvement, so far as the appearance of the urine was concerned—that is, the urine on each following day did not show any diminution in the amount of pus; patient, however, stated that he did not suffer as much pain, and that he could hold his urine better than he had been able to previous to using the antinosine solution. Encouraged by the improvement in the patient's subjective symptoms, he was kept on the irrigations. During the third week of the latter treatment it was observed that his urine seemed less cloudy and thick; this became more apparent at the end of a month's treatment, and at the end of six weeks treatment was suspended, the urine having become clear in color, normal in reaction, no triple phosphates present, and, in addition, the patient was able to control the passage of his urine. At this period the patient seemed entirely well of both cystitis and enuresis. Two weeks after discontinuing the irrigations the patient stated that the enuresis had returned, but not in an aggravated form, as only a few drops of urine passed at a time. He was again put on an antinosine irrigation; in this instance

it was thought best to irrigate only the urethra, as there was no indication, from repeated urinalysis, of the presence of any cystitis. An anterior urethral irrigation was used; this seemed to produce a slight irritation of the urethra at first. The pain was not severe, however, so there was no reduction made in the strength of the solution used. This treatment was continued for two weeks, the patient receiving an irrigation morning and evening. After the fifth day of the treatment incontinence of urine disappeared, but it was thought best to continue the irrigations until the inflammation of the urethra had disappeared. We judged that time to be when the solution did not irritate the urethra. At the end of two weeks the patient stated that he could hold his urine as well as ever, and he did not pass any urine during sleep—in fact, there was complete disappearance of all signs of enuresis.

This case will serve to illustrate the value of antinosine, not only for its immediate relief, but especially its ability to permanently relieve such conditions. It is now four months since the patient used any irrigation, and up to the present time he has not been annoyed in any way by his former condition—namely, cystitis or enuresis.

CASE II.—Charles M., aged thirty-five; native of New York; occupation, laborer; family history good. Habits: Does not drink alcoholic liquors to any excess; uses tobacco moderately; other habits fairly good.

Previous History.—Had the usual diseases of childhood; malaria several times; denies having had syphilis; states that he has had gonorrhœa several times.

Present History.—Patient admitted to hospital suffering with retention of urine. Examination of the urethra revealed organized strictures in the membranous urethra, a filiform sound being the only size which could be passed into the bladder. The patient was recommended for external urethrotomy. The operation was performed three days after entering the hospital. Two days after the operation the patient developed cystitis; this condition resulted from a drainage tube in the perineal section. For the cystitis a two-per-cent. solution of antinosine was used, the bladder being irrigated every day for twelve days. After the twelfth day irrigation was discontinued, the cystitis having disappeared.

CASE III.—In this instance no permanent benefit was obtained, as the condition which produced the existing cystitis was beyond medical or surgical interference, but in producing a temporary change, so far as the reduction of the pus in the bladder was concerned, antinosine solution had a very desirable effect, so I will submit this case purely upon experimental grounds: Richard F., aged sixty-four; colored; native of Missouri; occupation, laborer; no definite family or previous history obtainable.

Present History.—The patient complains of painful and frequent urination, having to pass his urine from fifteen to twenty times daily. Examination of the urethra reveals organized stricture in the anterior and membranous urethra, a small metal catheter being necessary to draw urine from the bladder. Examination of the rectum reveals enlargement of the prostate gland; in addition, urinalysis revealed a chronic interstitial nephritis. Urinalysis: Twenty-four hours' amount, twenty-six hundred cubic centimetres; cloudy;

reaction alkaline; specific gravity, 1.010; trace of albumin present. To obtain urine for examination for the presence of casts, the bladder was thoroughly irrigated, and two hours later urine was obtained by catheter; the specimens showed a few hyaline casts, no sugar, indican, or bile being present. In this case antinosine solution was merely used for the purpose of ascertaining its value of reducing pus in the bladder when it was associated with complications, such as a nephritis, without hope of permanently relieving the cystitis present, as the existing complications made that an impossibility. We began irrigating the bladder with a two-per-cent. antinosine solution; this was continued for two weeks. During that time the urine did not show as large an amount of pus as it did previous to the employment of antinosine. At the end of the above-named time the irrigation was discontinued. A week afterward a uranalysis was made; the urine had become thick, ammoniacal in odor, and contained a larger amount of pus than it did during the time irrigation was employed.

The rapid and satisfactory results shown in these few cases have been duplicated in the experience of some of the internes in the City Hospital, and there can exist no doubt whatever of the value of this remedy in cystitis more particularly, especially when of a purulent character. An advantage possessed by antinosine, which is not shared by other remedies which are used for the same purpose, is that it is positively non-toxic. There need be no hesitation in its employment, and instead of irritating it is soothing. Patients remark upon this and are pleased to have the injections administered. Another great advantage possessed by antinosine is its rapidity of action. I have had occasion to observe this, and also the fact that, a cure being well-established, it becomes permanent. It seems to fulfill the ideal requirements of a remedy so well expressed in the old Latin motto, "*tuto, cito et jucunde.*"

A CASE OF RIGHT LATERAL DISPLACEMENT OF THE BLADDER WITH FÆCAL IMPACTION.*

REPORTED BY MAJOR L. C. CARR,

BRIEFING SURGEON OF VOLUNTEERS,
COMMANDING UNITED STATES GENERAL HOSPITAL, GUANTANAMO, CUBA.

PATIENT, a medical officer of the volunteer army, forty-four years old; born in Guernsey County, Ohio. Father living and in good health, aged seventy-eight years; mother died in 1890, when sixty-eight years old, of an abdominal tumor, probably a carcinoma; four brothers and one sister living and in good health. Married; has four healthy children. From infancy he noticed a varicose condition of the veins of the right leg. Had an attack of pneumonia when he was about nine years old; typhoid fever at the age of eleven years; measles at fourteen years, and another attack of pneumonia at fifteen years. When seventeen years old he contracted intermittent malarial fever; then enjoyed good health up to the age of twenty-three years, when

he was attacked by yellow fever at Memphis, Tennessee. After this he enjoyed good health until he was thirty-six years, when he suffered an attack of sciatica of the right side, of a very mild form, lasting only twenty-four hours. After this the patient had several slight paroxysms of malarial fever, which readily yielded to treatment. He came to Cuba in August, 1898, enjoying perfect health, and on September 10th had an attack of malarial intermittent fever lasting thirteen days. The fever recurred in October and persisted several days. Another attack occurred November 4th, this time assuming a remittent type and lasting four days. On November 9th he was ordered to proceed to the United States in charge of the sick on a government transport. During his stay in the United States his health was good. He returned to Cuba in fairly good condition December 31st. Previous to his departure from Cuba he had noticed a swelling in the right iliac fossa. This swelling recurred once during his stay in the States, and again on his return voyage to Cuba. He left Santiago at 10 p. m. January 3d, 1899, en route to Guantanamo. During the sea voyage the patient was chilled, owing to the fact that his underclothing was of light grade and totally insufficient to keep him warm. During the night he rested badly, having frequent calls for micturition; he also had a severe attack of sciatica the following day. About twenty-four hours after landing he made a trip to Jamaica, ten miles distant, on an ambulance over a very rough road while still suffering from the sciatica of the right side. During the trip he made an attempt to pass urine at Jamaica, but without success. Upon returning to Guantanamo late in the evening of January 5th he was still unable to empty his bladder. A swelling appeared in the right iliac fossa, which gradually increased in size until it reached the line of the umbilicus, giving rise to great pain. There had been no passage from the bowels from the time of leaving Santiago, and large doses of salts, castor oil, and croton oil failed to overcome the constipation, although a slight liquid stool followed the use of the croton oil. The swelling continued to increase, accompanied by constant dribbling of urine. The sciatica became more intense. Hypodermic injections of morphine and atropine were given and inhalations of chloroform were resorted to. His condition grew gradually worse up to the time of his reaching the United States Army General Hospital, Santiago de Cuba, January 10, 1899, to which hospital he was sent with a diagnosis of fecal impaction and obstruction, with the previous message by cable to make preparations for a laparotomy. Immediately upon his arrival the commanding officer, in company with the entire medical staff, held a consultation on his case. The patient's condition was then as follows:

He was in great agony; temperature, 100° F.; pulse, 90; respiration, 18. His expression was cheerful and revealed but little sign of the intense agony above referred to, nor did he show the slightest apprehension of impending danger, although he was fully cognizant of the diagnosis of fecal impaction and of the further fact that all preparations had been made for laparotomy. There was no vomiting or retching. He only complained of slight colic now and then. The abdomen was rather distended and tympanitic; it contained a very marked tumor occupying the right iliac fossa, rather hard on pressure, movable, flat on percussion, and showing decided fluctuation on palpation; no desire to urinate existed. There seemed to be a general willingness to accept the diagnosis—fecal impaction—to the exclusion

* Transmitted from the office of the surgeon-general of the army.

sion of other trouble, when attention was called to the dribbling of urine, and Acting Assistant Surgeon F. W. Fabricius suggested the passing of a catheter before coming to a definite conclusion.

Catheterism was performed with the result of drawing sixteen hundred cubic centimetres of urine; this was only part of the contents of the bladder. The tumor disappeared immediately, and disseminated hard masses of fecal matter could be discovered in its place, proving beyond doubt that the tumor had consisted in greater part of the overdistended bladder. The second indication to meet, then, was to overcome the constipation, which had lasted for six days, and large enemata were given with good results. The patient rested easily until about midnight, when the catheter was again passed, drawing off twelve hundred cubic centimetres of urine. After this the patient slept tolerably well during the rest of the night. His temperature next day had dropped to 99° F. It rose again to 101° F. in the evening. The patient was catheterized every four hours. On the morning of the 14th his temperature was 99° F., and rose again to 100° F. in the evening. He then complained of burning pain when using the catheter, and began to pass bloody urine mixed with pus. The region of the bladder was very painful on pressure, indicating that acute cystitis had supervened. An irrigation of the bladder with a four-per-cent. solution of boric acid was made morning and evening, and the patient placed on a milk diet. His temperature on the morning of the 15th was 102° F., rising to 103° F. in the evening. Phenacetine was given until his temperature was reduced to 101° F., continuing at the same time the irrigations. The cystitis was greatly relieved by next morning; there was no pain on urination; the urine was no longer sanguinolent, and only contained some mucus. The temperature of the patient dropped to 99° F., and on the evening of the same day it was 98° F. During all this period rectal injections were continued with more or less success. Sulphate of magnesia was also administered. The bowels continued to act, but not freely, and, as no danger was imminent, and hard fecal masses were coming away at intervals, showing that the bowels were regaining their tonicity, heroic measures were not deemed justifiable. After the evening of January 16th the patient's temperature remained normal. In the meantime the sciatica had attacked the other side and was now double, continuing its nightly exacerbations. Phenacetine and quinine sulphate, in doses of five grains of the former and seven grains of the latter three times daily, were then prescribed and continued for several days, accompanied by daily applications of electricity.

From the periodicity of these attacks of sciatica, malarial infection was suspected. Several microscopical examinations of the blood were made. These examinations were negative, and malaria was excluded. Iodide of potassium in increasing doses was now prescribed, with a hypodermic injection of morphine during the exacerbations of the pain, especially at night, and the patient's condition improved so much that now he is able to sleep moderately well and walk about with comparative ease. He has been able to pass his urine without the use of the catheter on a few occasions, and also to do without the use of morphine.

The most striking feature of this case was the abnormal position of the bladder. Whether it was due to a congenital displacement or to the pathological condi-

tion of this organ is an open question. If we recall to mind the numerous attachments of the bladder to the surrounding parts, we can understand how difficult it must be for this viscus to get displaced even by mechanical causes. I have been unable to find any analogous case or any reference made to this condition in the medical works at our command. One of the chief objects of reporting this case is to suggest that it is of the utmost importance to bear in mind that this evidently was only one of the many anomalous conditions that might occur to mislead even the most careful diagnostician when called upon to perform a laparotomy in cases where there is undoubted intestinal obstruction, and to emphasize the importance of absolutely excluding every other possible complication before resorting to the knife.

This case was watched with much interest by every medical officer on duty in this hospital, as all of them were warm personal friends of the patient.

Therapeutical Notes.

Antiseptic Gelatin in Erysipelas.—The *Riforma medica* for May 2d ascribes the following to Gallois:

B Water	1,500 grains;
Gelose	15 "
Corrosive sublimate, { of each,	1½ grain.
Tartaric acid.	

For local application.

[Gelose is the active gelatinizing principle of the nutrient gelatin obtained from agar-agar.—Ed.]

An Aromatic Saline Bath.—The *Riforma medica* for May 1st ascribes the following to Loiret:

B Bromide of potassium	15 grains;
Carbonate of calcium	60 "
Sulphate of sodium	75 "
Phosphate of sodium	120 "
Carbonate of sodium	4,500 "
Essence of lavender	15 "
Essence of rosemary	15 "
Essence of thyme	15 "

For one bath.

An Application for Infantile Ecthyma.—Dauchez (*Bulletin général de thérapeutique*, March 15th; *Riforma medica*, April 6th) recommends the following application for favoring the detachment of the crusts:

B Glycerite of starch	60 parts;
Ammoniated mercury	1 part;
Sodium sulphite	10 parts.

M.

An Elixir of Hamamelis.—The *Riforma medica* for April 7th attributes this formula to Loiret:

B Fluid extract of hamamelis	3 parts;
Syrup of bitter-orange peel	50 "
Tincture of vanilla	2 "
Alcohol	18 "
Distilled water	27 "

M. A tablespoonful with each meal.

THE
NEW YORK MEDICAL JOURNAL.

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, JUNE 3, 1899.

THE VETO OF THE COLORADO MEDICAL BILL.

THE Cannon medical practice bill, which recently passed both houses of the legislature by a good majority, has been vetoed by the governor. The bill is spoken of by both the *Colorado Medical Journal* and the *Denver Medical Times* as a great improvement on the law now in force, although the first-named journal prints the following extract from a letter from Dr. J. T. Eskridge: "In regard to the medical bill, I worked for its passage, but felt all the time that it would be vetoed by Governor Thomas. Had the plain statements been inserted in the bill, excluding 'isms' and sects, religious, etc., the law would have been equally effective and would have received the governor's approval. Had he approved the bill as it passed the legislature, it would have caused many contests in the courts, as it was not clear from the wording of the bill just what 'ism' followers were allowed to vaunt their faiths. After so many of the physicians of Colorado made the statement in the daily papers that no one except followers of the three schools were included in the bill, had litigation been started subsequently it would have placed the medical profession in a bad light before the public."

But it appears to have been on no such consideration for the public welfare as Dr. Eskridge expresses that Governor Thomas founded his veto. Had he done so, or had he even vetoed the bill without giving his reasons, the medical profession of the State, although disappointed, would not have felt outraged, as it certainly does at present. We have seen only extracts from the governor's veto message, but they are enough to show that he took the occasion either to exploit certain crude and whimsical notions of his own or—and this seems the more likely—to bid for the political support of "every mountebank in Colorado," "every worn out prostitute posing as a magnetic healer," and "all the bigoted old Pharisees of 'Christian Science,'" as the *Denver Medical Times* puts it. In short, the governor of Colorado has abused and insulted the medical profession, and quite needlessly even from his own low point of view. It is hardly necessary to say to those who attended the Denver meeting of the American Med-

ical Association a year ago that Colorado has changed governors. It was most gratifying to listen to Governor Adams's just and appreciative words; it is humiliating to reflect that he has so soon been succeeded by a demagogue who, as the *Colorado Medical Journal* phrases it, rates the medical profession as "beneath the quacks, blacksmiths, Christian Scientists, pugilists, and gamblers."

PIED FORCÉ IN SOLDIERS.

MILITARY medical officers well know the trouble that is occasioned in troops on prolonged marches by a swollen condition of the feet, which has been the subject of many and various interpretations. The actual nature of these lesions has been carefully studied by M. Boisson and M. Chapotot, military medical officers of the French army, who report their results in a valuable paper in the *Archives de médecine et de pharmacie militaires* for February.

The condition itself has been described in turn by Pautat in 1857, Poulet in 1888, Martin in 1891, and Busquet in 1897. The principal characteristics are the supervention during a march of swelling on the dorsum of the foot, accompanied by pain more or less severe, either occurring spontaneously or provoked by pressure or movement, and functional incapacity. Pautat's explanation was that of traumatic periostitis, due, in his opinion, to the footgear and leading to exostoses on the second, third, and fourth metatarsals, those on the second being the most frequent; but he made no reference to crackling or crepitation, symptoms which, according to Boisson and Chapotot, are almost always present. The exostoses, however, he did not find in the earlier examinations, a fact which has considerable bearing on the authors' subsequent explanations. Poulet considered the lesions to be of the nature of rheumatic osteoperiostitis, and in his opinion the footgear was in no sense responsible, though he omits to say whether in his cases any history of traumatism was forthcoming. Martin referred the condition to arthritis and synovitis, as a result of eighteen observations. Finally, Busquet published in the *Revue de chirurgie* a memoir upon ossifying osteoperiostitis of the metatarsals, which he divided into three classes—viz.: 1. Direct primary, immediate, traumatic periostitis due to repeated slight shocks on the fore part of the dorsum of the foot. In this form the furrow in the upper leather of the shoe he considered to play an important etiological rôle. 2. Indirect traumatic periostitis. 3. Diathetic periostitis.

At the Congress of Hygiene and Demography, held

in April, 1898, in Madrid, Stechow, of the Prussian guard, made a communication on fractures of the metatarsals as a cause of swollen feet in soldiers. Concerning the mechanism thereof, Stechow says: If the heads of the first and fifth metatarsals are joined by a straight line, the heads of the others will make a salient angle in the form of a segment of a circle whose centre will be found in the anterior part of the first cuneiform, and whose radius will be about seven or eight centimetres. In the normal position the big toe and its metatarsal bear the shocks coming from in front, but when the inner edges of the feet are parallel, it is the second metatarsal whose head is in advance, and it is this or the others which will bear the brunt of a shock to the skeleton of the foot coming more or less from the side. Stechow, reasoning from skiagraphical examinations in thirty-six cases, arrived at the conclusion that in nearly all instances a fracture of the metatarsals was the cause of the injury under investigation. The left foot suffered more than the right, and the bones fractured were respectively as follows: First metatarsal, one; second, nineteen; third, fourteen; fourth, two. The authors, carrying on their researches from this point, endeavor to show that it is the act of marching to which these accidents, whether fractures or arthritis, must be attributed.

In all the cases examined by them in the great autumn manoeuvres of 1898 the second metatarsal was the seat of injury. Occasionally, also, the third suffered. The fracture always occurred in the continuity of the diaphysis, usually at the junction of the posterior third with the anterior two thirds, though at times in the middle. The fractures commonly occurred in a V shape, with the concavity forward. Sometimes the fragments were displaced, the branches of the V being more or less widely separated, and the anterior fragment somewhat deflected externally. In one case only was the fracture comminuted, and in no case was it transverse.

The rapid swelling, remaining for a long time, especially if the subject continues to march, the customary absence of ecchymosis, the support offered by the other metatarsals, and the small dimensions of the metatarsal diaphysis render it extremely difficult to elicit crepitation, which, however, may often be obtained by perseverance. An additional sign of the nature of the injury is to be found in pain on pressure over the seat of fracture and at a distance from the articular surfaces. A subjective sign of value in the diagnosis between fracture and arthritis is found in the fact that, in consequence of the support lent by the other metatarsals, it is possible for the soldier to raise himself on

tiptoe, which is impossible in arthritis in consequence of the pain occasioned.

As to the mode of production, the authors point out the immobilization of the second metatarsal by remarkably strong ligaments, by its position between the first and third cuneiforms, and also, when regarded from the inferior aspect, by its being locked between the tuberosities of the first and third metatarsals. The first metatarsal, on the other hand, is much more mobile. It moves in every direction on the first cuneiform, while the third is nearly equally movable. The fourth and fifth are the most movable of all. On the march, when the foot is firmly planted, the antero-posterior curve of the plantar vault tends to straighten itself, and the metatarsals glide over the tarsal facets. But in the case of the first metatarsal, which in progression gives the final point of support and serves almost exclusively for projection forward, we have to take into account the rigidity afforded by the powerful muscles whose tendons are inserted either at its posterior extremity or on the first cuneiform, thus assuring it the support of a tendinous network. Its own powerful flexors and extensors, moreover, contribute actively to this immobilization of the articular surface, especially as they contract in the execution of the movement.

The transverse arch of the plantar vault, maintained not only by the passive resistance of its ligaments, but also by the action of the abductor of the great toe and the tension of the peroneus longus, is equally subject to the influence of the weight of the man and his equipment. Consequently, any functional inefficiency of these muscles permits the flattening of the transverse plantar curve, and consequently the approximation of the second and third metatarsals to the plane upon which the foot rests. It is thus seen how the two concavities of the plantar arch may be depressed and flattened during the march. If, moreover, the muscles, tendons, and ligaments which fix the first metatarsal relax under the influence of fatigue, the latter, insufficiently sustained, tends to give way, leaving the resistance of the ground to act almost exclusively upon the extremity of the second metatarsal, which, by reason of its length, its comparative slenderness, and its proximity to the inner border of the foot, is found, fixed as it is at its tarsal extremity, in just the position to be broken under the conditions of a lever of the second order.

The authors next report cases and give Röntgen pictures showing the seat of fracture, and conclude that the condition known as *pied forcé* is always due either to fractures of the metatarsal diaphysis, principally the second, or to arthritis and strains of the metatarsal articulations; also that these conditions are to be attrib-

uted to marching in the way in which it is performed by soldiers—that is, for a prolonged time and weighted with equipment. On the other hand, when traumatism, falls, shocks, etc., occur, the type of fracture is modified, often involving the three central metatarsals. Overriding of the fragments and more or less marked articular lesions are often superadded, and when that is the case the effect is such as to render the subject unfit for military service. The “exostoses” described by Pauzat, (which were not found by him in the earlier examinations) are considered by the authors to be simply the callus formation at the seat of fracture, such as they themselves show, and which had hitherto been wrongly interpreted.

The condition described and explained by the authors is naturally not confined to military service. Many obscure cases of injury to the foot without any history of traumatism, in civil life, will no doubt receive elucidation by these researches.

THE WOMAN'S MEDICAL COLLEGE.

It is announced that the Woman's Medical College of the New York Infirmary for Women and Children closes its career with the expiration of the collegiate year. The closing of the school has been determined upon, not on account of anything unsatisfactory in its work or any present lack of patronage, but because of a frank recognition on the part of the trustees that the medical education of women can be better accomplished in another school, that of Cornell University, where they will be taught in the same classes with men, under the same faculty, and with the same clinical opportunities. The trustees add to their announcement an expression of their belief that the infirmary will hereafter be doing its best for the medical education of women by increasing its clinical facilities. Thus, we may suppose, the infirmary will speedily take an advanced position in the post-graduation instruction of medical women.

When Cornell University decided to establish in New York a medical school in which men and women would be taught together, the opinion was freely entertained that the institutions devoted exclusively to women students would find themselves under a competition that it would be very difficult for them to survive. From the sentimental point of view, this prospect was regretted even by the Cornell men themselves, for there has been unstinted recognition of the good work done by the Woman's Medical College for the last forty years; but it was felt, on the other hand, that there were really too

many schools in New York, and that the trustees and faculty of the Woman's Medical College would in fact loyally welcome the advent of an era of greater opportunities for the study of medicine by women. We may be allowed to say that the trustees have acted most creditably by doing promptly and spontaneously what they might otherwise have had to do eventually as the outcome of a struggle in which their resources might have been so taxed as seriously to impair the infirmary's usefulness.

The Woman's Medical College of the New York Infirmary for Women and Children has done a good work. Its memory will always be esteemed in the profession. No more graduates will go forth from its halls, but the diplomas it has already issued will be justly treasured by their holders and duly honored by medical men and women alike. We wish the infirmary all possible prosperity in its widened sphere of clinical teaching, and congratulate it on the wisdom displayed by its board of trustees.

MALARIAL DISEASE OF THE CENTRAL NERVOUS SYSTEM.

THE massing of Laveran's parasite in the blood-vessels of the central nervous system is among the rare events in pathology, as is remarked by Dr. G. Marinisco (*Comptes rendus de la Société de biologie*, 1899; *Medizin der Gegenwart*, May), who, in a recent post-mortem on the body of a woman who had suffered with malarial disease and died with symptoms of grave nervous disturbance, found the parasite so plentiful in the arterioles and capillaries of the brain and spinal cord that the gray substance was almost violet, and the white substance of a bluish gray.

THE RIGHT OF MUNICIPALITIES TO MAINTAIN HOSPITALS BEYOND THEIR OWN BORDERS.

WE are glad to be able to say that Governor Roosevelt has signed Assemblyman Henry's bill authorizing cities of the first class to maintain hospitals for the treatment of pulmonary consumption beyond their corporate limits. This will overcome any possible opposition to the establishment by the city of New York, for example, of such institutions in the Adirondacks and elsewhere in the State.

CORIAMYRTIN AS A MEDICINE.

THERE is reason to expect that this glucoside, though a violent poison, resembling picrotoxin in its action, may prove serviceable in the treatment of collapse. It appears from investigations by Ribem, Pernier, and Koppén, summarized in the *Klinische therapeutische Wochenschrift* for April 29th, that the dose in which it stimulates the respiratory and circulatory centres is less than that required to produce convulsions. Schenckelberg gives the maximum medicinal dose as fifteen one thousandths of a gram. Fischer has found it useful, combined with caffeine, in the circulatory disturbances that follow acute infectious diseases.

A NEW GERMAN SEMIMONTHLY.

We have received the first number of the *Deutsche Aerzte-Zeitung*, a double-columned royal octavo of twenty-four pages, edited by Dr. E. Stadelmann, of Berlin, and published in that city. It contains a number of interesting communicated articles, abstracts, and society reports, also a New York letter signed "Carl Beck." The new journal presents a very pleasing appearance.

THE REPORTED EXTENSION OF THE PLAGUE.

THE reported extension of the bubonic plague to Hong Kong and Egypt is rather disquieting. We have confidence, however, that it will not secure a foothold in Europe, and we trust that our sanitary service in the Philippines will prove equal to the task of keeping it away from those islands, although there has been scant time for methodical organization there.

THE REINA MERCEDES AND YELLOW FEVER.

It seemed at the time almost incredible that the people of Norfolk should object to the captured Spanish cruiser *Reina Mercedes* being taken to their city for repairs, as some of them are reported to have done, and we are glad to learn that they have since overcome their fears. It is understood that the surgeons-general of both the navy and the Marine-Hospital Service are satisfied, and with good reason, it seems to us, that the vessel is perfectly free from the germs of yellow fever.

THE NEW YORK QUAKERS ON VIVISECTION.

THE Friends of New York are to be commended for the moderation displayed in their recent reply to a communication from the Friends' Antivivisection Association of London. "We feel," they say, "that, while vivisection may be justifiable as a means of gaining knowledge for alleviation of disease, we believe the practice for the purpose of testing or illustrating what is already known to science should be discouraged and restricted."

YELLOW FEVER IN NEW ORLEANS.

It is reported that one case of yellow fever has occurred recently in New Orleans, and that the State board of health, on the strength of a post-mortem examination of the patient's body, has notified the boards of neighboring States, whereupon the State health officer of Texas has established a quarantine, and this in spite of an alleged agreement on the part of several of the Southwestern States not to take such action on account of the occurrence of a single case of the disease. We think the New Orleans health officer, Dr. Soneloh, was amply justified in sending to the Texas health officer the following dispatch: "I deeply regret your action. Send inspector to judge for himself. No other case anywhere."

THE NATIONAL COLLEGE OF ELECTRO-THERAPEUTICS.

THIS is the name of an institution in Lima, Ohio, which advertises that it gives a "mail course of instruction," but adds that "no instruction is given in medicine or surgery in the mail course." Some months ago

an individual living in Passaic, N. J., took the "mail course" and, on the strength of the diploma which was issued to him at its conclusion, began to practise medicine. He was accused of practising illegally, convicted, and sentenced. In his defense he had submitted the diploma in question, but it appears from an editorial in the May number of the *Electro-therapeutist* that the diploma did not purport to constitute its recipient a doctor of medicine. Nevertheless, the Passaic case has been made the basis of a number of articles in various medical journals reflecting upon the college. While we do not approve of "mail courses," and know nothing of the merits of the National College of Electro-therapeutics, we must say that the institution seems to have been unjustly criticised in this instance.

THE REMOVAL OF BELGIAN RESTRICTIONS ON AMERICAN CATTLE.

ACCORDING to a special dispatch to the *Sun*, the Belgian government has decided to discontinue the restrictions on the importation of American cattle. They were imposed five years ago and were founded, it is said, on the errors of Belgian veterinarians. The United States Bureau of Animal Industry has done incalculable good to the country in various matters, and now it is probably to be credited with bringing about this reestablishment of justice in Belgium.

THE HEARING IN LOCOMOTIVE EMPLOYEES.

MUCH attention has been paid of late years to the subject of color-blindness in railway employees, but not so much, so far as we have observed, to the acuity of their hearing. Dr. V. Saxtorph Stein (*Nordiskt medicinskt Arkiv*, April) has examined forty-four firemen and thirty-eight engine-drivers, and found only three out of the whole number to possess perfectly normal hearing power. He finds, however, by frequent excursions on locomotives, that these employees hear sound signals well enough under favorable circumstances, except those of the whistle. Nevertheless, he thinks there should be established a minimum standard of requirement as to the hearing.

AGRICULTURAL LABOR FOR LUNATICS.

At the recent meeting of the American Medico-psychological Association Dr. G. Alder Blumer, of the Utica State Hospital, read a paper entitled *The Care of the Insane in Farm Dwellings*, in which he told of the good effects upon a number of chronically insane men of daily work on a farm under the supervision of a young farmer and his wife who had no special knowledge regarding the care of the insane. The improvement in the patients' condition, physical and mental, said Dr. Blumer, "exceeded the most sanguine expectations." This seems to us a line of inquiry well worthy of further pursuit.

A GRAVE ACCUSATION AGAINST TWO PHYSICIANS.

THE press dispatches state that two physicians have been arrested in Rhenish Prussia charged with having caused the death of several recruits by drugging them for the purpose of securing their exemption from military service. It is difficult to believe that members of our profession would engage in any such work, or, having entered upon it, would conduct it so recklessly as to

give rise to the fatal results reported. We hope to see the accused physicians cleared of the charge.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 27, 1899:

DISEASES.	Week ending May 20.		Week ending May 27.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	12	8	58	4
Scarlet fever.....	196	14	212	17
Cerebro-spinal meningitis.....	0	8	0	7
Measles.....	438	18	404	16
Diphtheria.....	219	25	238	31
Croup.....	13	10	12	4
Tuberculosis.....	170	141	169	141
Small-pox.....	1	0	12	5
Chicken-pox.....	32	0	34	0

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general during the week ending May 27, 1899:

Small-pox—United States.

Los Angeles, Cal.....	May 6-20.....	4 cases.

St. Vincent's Hospital.—The new wing was formally opened by Archbishop Corrigan on Decoration Day. The ground floor contains casualty wards, St. Antony's ward with nine beds, furnished by Miss Teresa O'Donohue, receiving rooms, pharmacy, and dispensary. On the next floor are the parlors, St. Teresa's ward and St. Aloysius's ward, containing thirty-one beds, furnished by Mrs. Teresa R. O'Donohue and Miss Eleanor Iselin. On the floor above are St. Vincent de Paul's ward and St. Joseph's ward, furnished respectively by Mrs. John Beresford and the Rev. Dennis P. O'Flynn; on this floor also are the medical officers' quarters. Higher still are St. Adrian's, St. Ambrose's, and St. Lawrence's wards, containing forty-one beds and furnished respectively by Mrs. de Lancy Kane, Mrs. Jeremiah Campion, and Miss Teresa Iselin; there are also private wards on this floor. The fifth story contains St. Margaret's, St. Helena's, and St. Rose's wards, containing in all forty-one beds, and furnished respectively by the Ladies' Auxiliary, Mrs. Iselin, and Mrs. A. L. Ashman; also private wards. The sixth floor, St. Matthew's Hall, is furnished entirely for the occupation of the Sisters by Matthew Rowan. On the top floor is an admirably constructed operating theatre, generously equipped by an anonymous doctor, with anæsthetizing rooms, sterilizing chamber, X-ray apparatus, surgeons' dressing and bath rooms, etc. The new wing will prove a great addition to the charitable institutions of the city.

A Plague Quarantine at Malta.—According to the *Sun*, passengers arriving at Malta on vessels from Egypt must swear that they have not been in Egypt within twenty-one days, or else undergo quarantine on ship-board for that length of time.

The German Medical Society of the City of New York.—At the next regular meeting, on Monday evening, June 5th, Dr. Hermann Kahn will present an instance of a child born alive and almost at term, weighing less than a pound; Dr. Max Einhorn will read a paper on Floating Liver and its Clinical Significance; Dr. C. H. Richard Jordan will read one on The Surgical Treatment of Suppuration of the Ear; and Dr. W. Freudenthal will present one on The Nature of the Diseases reputed to be Due to Exposure to Cold.

The Ontario Medical Association will meet in Toronto on Tuesday and Wednesday, June 13th and 14th.

The Buffalo Academy of Medicine.—A special meeting was held on Thursday, May 25th, for the purpose of taking proper steps to secure the meeting of the American Medical Association in Buffalo, June 1, 1901 (Pan-American year).

The Alumni Association of the College of Physicians and Surgeons is reported to have received at a recent meeting to set up in the college building a tablet commemorative of those of the alumni who lost their lives in the service during the recent Spanish-American war.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, May 27th, Dr. John Young Brown reported a case of pyometria.

Changes of Address.—Dr. Herman B. Baruch, from June 1st to October 1st, corner of Cedar and Second Avenue, West End, Long Branch, New Jersey; Dr. J. H. Porman, to No. 2313 Seventh Avenue, New York; Dr. S. A. Knopf, to No. 16 West Ninety-fifth Street, New York; Dr. J. A. Shears, to No. 319 West Thirty-third Street, New York.

Erratum.—In our issue for May 27th, on page 749, there appeared an article headed Muscular Atrophy of the Skin. The first word of the title should have been *macular*.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending May 27, 1899:*

PALMER, S. B., Assistant Surgeon. Resignation accepted from May 15th.

ARNOLD, W. F., Passed Assistant Surgeon. His leave of absence on account of sickness is extended two months.

DE LANCY, C. H., Assistant Surgeon. Detached from the marine recruiting rendezvous, Savannah, and ordered to the *Amphitrite*.

MAKSTELLER, E. H., Surgeon. Detached from the *Raleigh* and ordered home to await orders.

MOORE, J. M., Passed Assistant Surgeon. Detached from the *Raleigh* and ordered home to await orders.

ROGERS, F., Surgeon. Ordered to the marine rendezvous, Philadelphia, for duty in connection with recruiting.

Appointment.

WRIGHT, BARTON L., Assistant Surgeon. May 16th.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the Marine-Hospital Service for the Seven Days ending May 18, 1899:*

MURRAY, R. D., Surgeon. Upon being relieved from duty at Mobile, Alabama, and upon expiration of leave of absence granted by bureau letter of the 11th inst., to proceed to Key West, Florida, and assume command of the service.

GODFREY, JOHN, Surgeon. Bureau order of May 10, 1899, directing Surgeon Godfrey to report to the chairman of the board of examiners at Detroit for examination to determine his physical condition, revoked.

MEAD, F. W., Surgeon. Upon being relieved from duty at Portland, Maine, to proceed to Vineyard Haven, Massachusetts, and assume command of the service.

PECKHAM, C. T., Surgeon. Relieved from duty at Pittsburgh, Pennsylvania, and directed to proceed to Galveston, Texas, and assume command of the service.

WHITE, J. H., Surgeon. To proceed to New York for special temporary duty.

MAGRIDER, G. M., Passed Assistant Surgeon. Granted leave of absence for thirteen days from May 19, 1899.

SMITH, A. C., Passed Assistant Surgeon. To rejoin station at Norfolk, Virginia, reporting at Washington, D. C., en route.

EAGER, J. M., Passed Assistant Surgeon. To proceed to Detroit, Michigan, and report to medical officer in command for duty and assignment to quarters.

STEWART, W. J. S., Passed Assistant Surgeon. Upon being relieved from duty at Vineyard Haven, Massachusetts, to proceed to Mobile, Alabama, and assume command of the service.

THOMAS, A. R., Assistant Surgeon. Bureau letter of March 30, 1899, directing Assistant Surgeon A. R. THOMAS to proceed to the Tortugas Quarantine Station and assume command of the service, revoked.

CUMMING, H. S., Assistant Surgeon. Granted leave of absence for one day. Bureau order of March 30, 1899, assigning Assistant Surgeon CUMMING to duty at the Cape Charles Quarantine, revoked. Upon being relieved from duty at Norfolk, Virginia, to proceed to the South Atlantic Quarantine Station and assume command of the service. Granted leave of absence for twenty-seven days.

CLARK, TALLAFERRO, Assistant Surgeon. Upon being relieved by Assistant Surgeon H. S. CUMMING, to report to him for temporary duty. Relieved from duty at the South Atlantic Quarantine Station and directed to proceed to the Tortugas Quarantine Station and assume command of the service.

McMULLEN, JOHN, Assistant Surgeon. Relieved from duty as sanitary inspector on United States transport *Buford* and directed to report to medical officer in command, United States Marine-Hospital Service at the Immigration Depot, New York, for temporary duty. Relieved from temporary duty at the Immigration Depot, New York, and directed to proceed to Portland, Maine, and assume temporary command of the service.

ANDERSON, J. F., Assistant Surgeon. To proceed to Norfolk, Virginia, on special temporary duty, and then to proceed to New York and report to medical officer, Marine-Hospital Service, at the Immigration Depot for temporary duty.

McADAM, W. R., Assistant Surgeon. Relieved from duty at Key West, Florida, and to continue in temporary charge of the Tortugas Quarantine Station. To report to medical officer in command, Tortugas Quarantine Station, for duty.

CRAIG, R. C., Acting Assistant Surgeon. Relieved from duty at New York and directed to proceed to Pittsburgh, Pennsylvania, and assume temporary charge of the service.

BIRFORD, R. E. L., Sanitary Inspector. Granted leave of absence for thirty days on account of sickness. Bureau order of May 19, 1899, convening a board of officers of the service to meet at Detroit, Michigan, for the physical examination of GODFREY, JOHN, Surgeon, revoked.

Appointments.

MERRILL, WALTER E., of Maine, appointed acting assistant surgeon, United States Marine-Hospital Service, for duty at Portland, Maine. May 11, 1899.

HENDERSON, W. S., of Michigan, appointed acting assistant surgeon, United States Marine-Hospital Service, for duty at Port Huron, Michigan. May 11, 1899.

Society Meetings for the Coming Week:

MONDAY, June 5th: American Academy of Medicine (third day); American Medical Publishers' Asso-

ciation (Columbus); New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, New York, Academy of Medicine; Utica, New York, Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

TUESDAY, June 6th: American Medical Association (first day—Columbus); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, New York, Academy of Medicine; Ogdensburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Societies of the Counties of Franklin (semiannual), Herkimer (quarterly), Niagara (annual—Lockport), Saratoga (annual), and Yates (annual), New York; Hudson (Jersey City) and Warren (annual), New Jersey, County Medical Societies; Androscoggin, Maine, County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, June 7th: Maine Medical Association (first day—Bangor); American Medical Association (second day); New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, New York (New Brighton); Penobscot, Maine, County Medical Society (Bangor); New Hampshire State Medical Society (annual—Concord); Orleans, Vermont, County Medical Society (annual); Bridgeport, Connecticut, Medical Association.

THURSDAY, June 8th: Maine Medical Association (second day); American Medical Association (third day); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; New York Laryngological Society (New York); Medical Societies of the Counties of Cayuga, Cortland (annual), and Fulton (semiannual), New York; South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

FRIDAY, June 9th: Maine Medical Association (third day); American Medical Association (fourth day); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, New York.

SATURDAY, June 10th: Obstetrical Society of Boston (private).

Births, Marriages, and Deaths.

Married.

ARMSTRONG—KENDALL.—In Brooklyn, on Monday, May 29th, Dr. William L. Armstrong, of New York, and Mrs. William B. Kendall, Jr.

BARRAS—LOWE.—In New Orleans, on Monday, May 22d, Mr. Valtrine Barras and Miss Bertha Lowe, daughter of Dr. M. M. Lowe.

EDWARDS—SOUTTER.—In New York, on Monday, May

29th, Dr. James Clifton Edgar and Miss Ellen Muriel Beatrice Soutter.

HOLDEN—MEAD.—In New York, on Tuesday, May 16th, Dr. Eugene Martin Holden, of Boston, and Miss Ida Frances Mead.

WARNER—MILLER.—In Glens Falls, New York, Dr. Harry Mead Warner and Miss Harriet Esther Miller.

WEBSTER—LUSK.—In New York, on Saturday, May 27th, Dr. Clarence Webster, of Montreal, and Miss Alice Lusk, daughter of the late Dr. William T. Lusk.

Died.

EDMONDS.—In Bristol, Vermont, on Tuesday, May 23d, Mrs. G. F. Edmonds, wife of Dr. George F. Edmonds.

HARGIS.—In Pensacola, Florida, on Wednesday, May 24th, Dr. Robert W. Hargis, aged fifty-three years.

MOIR.—In Edinburgh, Scotland, Dr. John Moir, F. R. S. E., in the ninety-second year of his age.

PFEIFFER.—In New York, on Monday, May 22d, Dr. Charles W. Pfeiffer, in the forty-sixth year of his age.

SHOWERMAN.—In Batavia, New York, on Thursday, May 25th, Dr. James M. Showerman, in the sixtieth year of his age.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL.B.

XXI.

RECOVERY OF COMPENSATION.

(Continued from page 756.)

Proof of Employment.—The physician having shown himself authorized to practise medicine, the next step in establishing his right to recover is to show his employment. If the suit is instituted for the purpose of recovering for services rendered to the defendant himself or any immediate member of his family for whose medical services he is primarily responsible, then the mere fact of the services having been rendered by the physician and accepted by the patient is sufficient to establish employment. If, however, the services have been rendered to some third party, for whose medical attendance the defendant is not primarily liable, this step in proving the case may require great care and skill. The law governing liability in such cases is fully treated in a preceding article.

Proving Services Rendered. Having passed very briefly over the method of proving the physician's right to practise medicine, and his proof of employment, we will pass to the next and, to him, more important step of proving the services rendered.

The question of how far a physician may go in giving testimony upon this point is often a very nice one, for the statutes of many States place a seal of secrecy upon the lips of the physician with regard to knowledge obtained in a professional way. The Civil Code of New York provides that a physician "shall not be allowed to disclose any information on which he is engaged in attending a patient in a professional capacity and which was necessary to enable him to act in that capacity." In

New York a physician brought a suit to recover for services, and the patient filed a general denial to the physician's complaint or preliminary statement of facts upon which he relied for recovery. The question then arose as to what facts the physician would be permitted to testify to under the law from which this quotation is taken. He attempted to, and, in fact, did, in the trial court testify to the defendant's physical condition and the disease for which he treated him; but upon appeal the judgment was reversed because the physician had no right, under the law above quoted, to disclose such information, the patient not having waived his privilege. It was urged by the physician's counsel that the patient, by his general denial, waived the privilege. The court, however, held this ground to be untenable, notwithstanding the general denial did make it incumbent upon the physician to prove all of the facts upon which he based his case; had, however, the patient set up, as a defense, incompetency, unskillfulness, or misconduct, he would then have put in direct issue the manner of treating the disease, and would doubtless have been held to waive the privilege, thereby permitting the physician to testify to the condition he found existing in the patient and to the treatment which he prescribed. It was also urged in this case that if the physician were not permitted to describe the disease with which the patient was afflicted he could not show the value of the services, but the court was of the opinion that such a result did not necessarily follow. Justice Haught, who wrote the opinion, said: "The physician can still testify to his employment, to the number of visits made, to the examinations, prescriptions, and operations, and if the defendant objects to his describing them the physician may testify as to their value."^{*}

This rule would preclude the physician from corroborating his testimony as to the value of the services because he could not communicate the character of the services rendered to another physician to enable him to form an opinion as to their value; but it is obvious that the defendant could not produce a witness to dispute the value of such services without making public the facts which the plaintiff was forbidden to disclose, thereby enabling the plaintiff to produce expert evidence in corroboration of his own testimony as to the value of the services rendered.

Books of Account in Proving Claims.—Unless the services upon which the suit is brought have been very recently rendered it will be extremely difficult, if not impossible, for the physician to testify to the time of making each visit and the value of the same without having recourse to his books of account.

At such a time the physician's books of account may generally, if properly kept, be made use of for a double purpose: first, they may be used to refresh the mind of the physician in testifying to the facts referred to therein, and, second, they may be introduced as evidence to prove the account upon which suit is brought. As a means of refreshing his memory, it is proper for a physician upon testifying to have recourse to his books either where he recollects the facts and can testify from memory, or where he does not recollect the facts, but made or saw the writing when the facts were fresh in his mind and remembers that it then stated the facts correctly.[†]

No general rule can be given as to when, where, and

under what circumstances the books of account are admissible as evidence of the facts stated in them, as the subject is one upon which the decisions from the courts of the several States are irreconcilable; moreover, many States have statutes regulating the subject which are peculiar to the particular jurisdiction. In New York the physician's books of account are admissible as evidence upon his showing them to be his regular books of account, and proving that he kept no clerk who was familiar with his business and competent to testify regarding the facts stated in the books; that some of the work or services charged was performed, and that he kept correct accounts.^{*} The proof that the physician keeps correct books of account should be made by patients who have settled bills by his books.[†] The physician's wife, who transcribes or enters items into the physician's books, is not a clerk within the meaning of the above qualification.[‡] In Pennsylvania the physician's books of original entry are admissible in evidence upon being properly proved to be such.[§] In Indiana it is very doubtful whether books of account are competent evidence.^{||} The rule as it exists most generally is that the books of original entry are admissible when properly proved. If the entries are in the handwriting of the party himself, then he may prove the same; if in the handwriting of a clerk, then such clerk must identify or prove the account; but if the person who made the entries is dead, mentally incapacitated, or beyond the jurisdiction, the books may be received in evidence upon proof of the handwriting of such person.[^] This rule must, however, be understood as subject to many qualifications and exceptions.[◊]

It is generally required that the books be those of original entry. Such is the requirement in many of the States.[‡] In Pennsylvania it is held that a book containing entries transferred from time to time, as the parties had leisure, from a blotter, which is preserved and in the possession of the party offering the book, is not admissible as a book of original entries, the blotter being the permanent record of the transaction.[§] If, however, such entries are first made upon slips of paper or cards and then copied into a book, such book becomes one of original entries.^{||} If these temporary memoranda are made by one person and transcribed into the book by another, it will probably be necessary to call not only the person transcribing them to prove the entries made in the book, but persons making the original memoranda as well, to prove that at or about the time the charges were made services were performed similar to those charged in the book.^{**}

Books of Account, How to be Kept.—It is advisable

* Van Allen vs. Gordon, 83 Hun., 379; 31 N. Y. Supp., 907.

† Chase's *Stephen's Dig. of Evidence*, Art. 137, N.

to refer at this point to the manner and method of keeping the physician's books of original entry. It has been observed that a physician may be required to state specifically the nature of each service rendered and charged upon the account, especially if the amount charged for the same is of an unusual character; it therefore is necessary that some explanation be entered with each item which will enable the physician to refresh his memory and testify to the particular services rendered.

Upon the other hand, if the books are desired to be used in evidence in those States extending to professional communications between physician and patient the privilege of secrecy, they must not divulge matters coming within the protection of the statute, otherwise they will be objectionable and will be excluded upon motion of the patient or his personal representatives. Generally speaking, any information obtained by the physician in his professional intercourse with his patients which was necessary to enable him to treat them, and also the character of treatment advised or prescribed by him, are within the protection of the statute.* Here is clearly a case where the requirements of the law on the one hand, and the prohibition of the law upon the other, conflict in such a way as to subject the physician to a severe hardship. This hardship it is thought may be overcome if the physician living in a State which enjoins silence as to all knowledge professionally obtained will invent a code of arbitrary signs and characters, and by the use of these characters describe the ailments for which he treats his patients, together with the services rendered by him. Such characters when used must, however, be completely unintelligible to others, and it can not be safely advised that he would be permitted to disclose his system to another and still claim the privilege of having his books containing such characters admitted in evidence.

Illustrations.—Should the physician have been so indiscreet as not to keep a book of accounts, and is unable to recall and testify specifically to the items of the account upon which he brings suit, or is prohibited from so doing by reason of the death or mental unsoundness of the patient, his ability to recover is a matter of very grave doubt. In the case of *Administrator, etc., of Galtney vs. Leggett*, Dr. Leggett brought suit to recover among other sums one upon an open account for medical services rendered Galtney and his wife, children, and servants during the years from 1836 to 1842, and which amounted in the aggregate to one hundred and forty dollars. Leggett's only witness was John W. Monnett, Galtney's regular family physician, by whom it was proved that Leggett attended Galtney's family in his absence. He testified that he had seen Leggett at Galtney's house two or three times, but did not say at what time. He did not know anything about any of the charges made, nor of Leggett's making any visits at the time charged; he knew nothing of the items; that he had heard Galtney frequently say that he had employed Leggett as his physician when he was absent; that Galtney's family, white and black, numbered nearly one hundred persons, and they were often sick; that he had called two or three times in consultation with Leggett at Galtney's house; that the prices charged for the services were according to the usual rates; that Galtney and Leggett were very intimate, and that it was not unusual

for men situated as they were to suffer accounts to run on uncollected for a long time. Justice Thatcher, in commenting upon the case, said: "The evidence, however, upon which the jury found for the plaintiff some portion of the account for medical and surgical services seems extremely vague and uncertain. The only witness called by the plaintiff to establish this account could speak neither as to the time or the character of the services charged, and, in point of law, gave no testimony as to the account filed. It is true that it is difficult for accounts of this character to be strictly proved, nor indeed is it necessary; but it would seem to be always in the power of a physician or surgeon to show that he was in the habit of keeping correct books of accounts, and that the account sued upon had been correctly copied from his books. It is also true that the court will not lightly disturb the findings of a jury in cases of this kind where they are particularly the proper judges of the weight of the evidence; but in the present instance the evidence does not seem at all to warrant the verdict upon the account."

And, again, in the case of *Simmons vs. Means*, in which suit was brought to recover a hundred and fifty dollars for medical services generally and medicines furnished to defendant and his family, and in which the jury found a verdict for the plaintiff for a hundred and thirty dollars, the evidence showed that during the period charged in the account the plaintiff was the family physician of the defendant, and was seen several times going to and from the defendant's residence, and was frequently at the house of the defendant; and that the charges contained in the account filed were in accordance with the customary rates in that locality.

Justice Thatcher, passing upon this case, also said: "The evidence introduced to prove the account was to the effect that the plaintiff below was the practising physician in the family of the defendant, and that he was seen passing to and from the defendant's house, during the time included in the account; and that 'he did practise in his family' during the period, together with proof that the amounts charged in the account were according to the customary rates. The items of the account do not appear in the record. The bill of exceptions does not show of what character the professional services or medicines supplied were, or that any, in fact, were supplied. The evidence that the physician practised in the family, and was seen going and returning from his house, is not sufficient to create a legal presumption of indebtedness by the defendant. This court has gone so far as to authorize a physician to recover in an action against his patient by establishing upon a trial the facts of his habit of keeping correct books of accounts, and that the account sued upon had been correctly copied from his books. But with this exception, physicians must be held, like others, to the customary rules of evidence. In this view the finding (of the jury in favor of the physician) in this case was plainly unwarranted by the evidence."*

Nor has the jury any right to assume, because most of the items of such an account have been positively proved to be correct, that all of the items are correct. The court, in a case involving this point, said through Justice Fisher: "The plaintiff must either prove his account by direct and positive proof, or show that he keeps correct books, and that his accounts have been correctly transcribed."

* The subject of privileged communications will be fully treated in further articles about a full list of the States in which such law in force will be given.

* *Simmons vs. Means*, 10 Mass. 117.
1 Mass. 117. 1841.

And, again, in the case of *Déjol vs. Johnson*, admr, in which a physician's bill had been allowed and paid to the amount of \$612.55, Justice Spofford said: "The large medical bill is not justified by the evidence. There is no detailed account of items. Two or three visits to the parish of Calcasieu, about forty miles from Dr. Thornton's residence in Flat Town, and constant attention to the deceased for a fortnight in his own house, whither *Déjol* was removed before his death, together with the furnishing of medicines, are all the services specifically proved. It is true a witness states that the doctor attended the deceased for six or eight months before his death. The disease was also a loathsome one. But the opinion of this witness that the bill was a just and correct one can not supply the lack of data to support such an opinion. Upon a survey of the evidence we are satisfied that three hundred dollars would be a liberal allowance for the services as proved, and the item charged as paid to Dr. Thornton must be reduced to that sum." *

In proving that professional services have been rendered, it is competent for the physician to produce a witness to testify that the physician left his office, taking medicine with him, and said he was going to visit the particular patient, and started in the direction of the place where he lived.† It will be understood from the preceding cases that this evidence is simply corroborative in effect and is valuable only for the purpose of strengthening the evidence of the principal witness who testifies as to the particular services rendered.

Proof of Amount of Claim.—There is no presumption of law concerning the value of a physician's or surgeon's services, and there is no presumption that a jury can ascertain it without testimony of some kind from persons knowing something about such value.‡ It has been shown that the plaintiff is a competent witness to testify to the value of the services which he has sued to recover, the patient being alive and of sound mind. Should any other physician be cognizant of the character and extent of the services upon which suit is brought, it will also be competent for him to testify to their value; or, if the case is such that the plaintiff is not precluded from disclosing the character of the defendant's disease and the nature and extent of his services, then he may call upon any regular physician to testify as to their value. When such testimony is given regarding the value of the services rendered and none is given to contradict it, the jury is not permitted to disregard the evidence and form an independent conclusion, but must find in accordance with the evidence.¶ Should conflicting evidence upon this point be adduced by the parties, it then becomes the duty of the jury to scrutinize it and deliberate upon the matter with care, so as to arrive as nearly as possible at the true value of the services performed.

The supreme court of Louisiana lays down the rule that where the witnesses differ as to the proper charges to be made by physicians, the correct rule is to allow the lowest estimate.||

Should the case be one of a difficult operation, and the ability and professional standing of the physician specially high, these facts are proper for the considera-

tion of the jury and will justify a greater compensation.* A witness who is produced to show the value of the services in question must testify regarding the value of the particular services upon which suit is pending or those of the same character.† It is not necessary that the physician should prove the value of the services to the patient, the value to be proved by him is the ordinary and reasonable price for services of that nature.‡ The reasonableness of the charges can not be established by a witness proving what the same physician had charged him in a similar case,§ nor is one not a physician competent to testify as to the value of such services.|| While in epidemics custom may sanction an increased rate of charge, such conditions will not justify exorbitant fees, and in estimating the correct amount the court is inclined to the lowest estimate given by witnesses.△

(To be continued.)

Pith of Current Literature.

Airol as an Application in Rupture of the Perinæum.—Dr. M. Ebersson (*Therapeutische Monatshefte*, January; *Wiener medizinische Blätter*, April 13th) finds airol superior to iodoform as an application to perineal ruptures that have been sutured, but he advises that it be used sparingly; otherwise, like iodoform, it will cake and obstruct the escape of discharges.

"Phosote," a New Creosote Compound.—The *Klinisch-therapeutische Wochenschrift* for April 30th says that the French have given the name of "phosote" to a creosote ether containing eighty per cent. of creosote and twenty per cent. of phosphoric anhydride. It is described as a syrupy liquid having a faint odor and taste of creosote. It is employed in tuberculous disease like creosote carbonate and oleate and the corresponding compounds of guaiacol.

Trichloroacetic Acid for Persistent Perforation of the Membrana Tympani.—Dr. Felix Pettesohn (*Berliner klinische Wochenschrift*, 1899, Nos. 15 and 16; *Wiener klinische Rundschau*, May 7th) reports a gratifying degree of success in causing perforations of the membrana tympani to close by the employment of Okuneff's method of canterization with trichloroacetic acid. The acid is applied to the cicatrized border of the perforation, and, according to the effect produced, the canterization is repeated in four, eight, or fourteen days, care being taken not to apply it too often. The pain is severe, but lasts only a few minutes. In case a scab forms, it is well to wait for its spontaneous detachment.

Resuscitation from Drowning by Rhythmical Traction on the Tongue.—According to the *Medical and Surgical Review of Reviews* for April, citing the *Tribune médicale* for January 18th, one evening two boatmen heard a body fall into the water. In consequence of the darkness several minutes elapsed before they found and pulled out a young woman, who was absolutely inert,

into their boat. Immediately, without returning to land, they opened her mouth with the handle of a knife placed between the teeth, and practised rhythmical traction of the tongue, following the prescribed directions to get rid of the imbibed water. After ten or twelve minutes she regained consciousness.

Resuscitation in asphyxia and in threatened death during anaesthesia by rhythmical tractions on the tongue was introduced a few years ago by Laborde. The writer in the *Tribune* comments on the importance of at once seizing the tongue and practising tractions without waiting to carry out any of the traditional directions, as to the position of the body, removal of clothes, etc.

Diaphragmatic Pleurisy.—Zuelzer (*Münchener medizinische Wochenschrift*, November 22, 1898; *Canada Lancet*, March) gives a description of pleurisy as it occurs between the diaphragm and the lung; a form which is very apt to give rise to localized encapsulated empyemata. There are certain special characteristics which enable the diagnosis of this condition to be made even in the absence of physical signs. These consist chiefly in certain tender points. The first is round the base of the thorax at the level of the insertion of the diaphragm; the second is in the posterior triangle of the neck, where the phrenic nerve lies on the scaleni muscles; and the third is found where an imaginary line prolonged in the direction of the tenth rib cuts the parasternal line. It was first described by Guéneau de Mussy and named by him the "*bouton diaphragmatique*." The presence of tenderness and pain in this position is most important, and is almost pathognomonic of diaphragmatic pleurisy, more especially of the localized suppurative form. Dr Mussy and most writers since him have considered this to be the tender point of the phrenic nerve, though von Ziemssen disputes this on the ground that the function of this nerve is entirely motor. Other peculiarities of this variety of pleurisy are: 1. The pain is abnormally violent and diffuse. 2. Movement is almost suppressed in the hypochondrium and base of the thorax on the affected side. 3. Physical signs may be absent, or consist in a limited tympanitic resonance at the extreme base, and *minus* breath sounds, owing to the compression of the lung by the effusion. 4. Occasionally there is pain on swallowing as the food passes the diaphragm. 5. Hiccough may be present, either from direct irritation of the diaphragm, or possibly of the vagus or phrenic nerves.

It is important to remember that these effusions, when near the centre of the diaphragm, are out of reach of the exploring syringe. One of the cases seen by the writer gave a striking illustration of the value of de Mussy's point in diagnosis. A woman, aged thirty, fell ill with fever and pain in the breast. There were no abnormal physical signs in the lungs, and an exploratory puncture gave a negative result; the phrenic nerve in the neck, however, was tender and the *bouton diaphragmatique* extremely painful, and by these symptoms alone Dr. Bonveret, of Lyons, diagnosed supplicative diaphragmatic pleurisy, and immediately handed the case over to the surgeon. An encapsulated empyema was found and evacuated. The woman recovered.

The Difference between the Effects of Mental Overwork and Worry on the Child and on the Adult. Dr Graham Brown (*Scottish Medical and Surgical Journal*, May), in an article on Treatment of Diseases of the

Nervous System, says that there is a curious difference between childhood and adult life as regards the effect of mental work and of worry on the brain. In the adult it is difficult to injure the brain by overwork, because, when a certain intensity of strain has been reached, the brain refuses to work any longer and the man is forced to rest. On the other hand, it is quite easy to do serious injury to the brain of a child by pressing him in regard to mental work, and this happens even more readily in neurosthenics than in healthy children. The reverse is the case with regard to worry. This falls lightly on a healthy child, and the most serious trouble may at any time be dissipated by the administration of a sugar plum. In a man, on the other hand, cares and worries are not readily shaken off. The mind can not easily forget them, and sleep is interfered with. A neurotic child takes an intermediate position in this matter. Worries and anxieties are apt to fix themselves in his mind in a quite morbid fashion.

In conclusion, a word may be said as to mental work and mental exhaustion in neurotic children. Even in the perfectly healthy child we know from many observations that an hour or two of such work produces an exhaustion which is quite perceptible in that it blunts the tactile sense to a degree capable of being measured. In neurotics exhaustion of the cortex is even more readily produced, the visual field, for example, becoming distinctly smaller. This points to the necessity of making the periods of work of a neurotic youth short, and of interposing muscular exercise between each. It might be possible in any individual case, by direct testing of the visual or tactile sense, to say whether too much exhaustion was being occasioned, or, in other words, whether the mental work done was proving too much for the boy.

The Micro-organism of Scarlet Fever.—At a recent meeting of the Chicago Medical Society Dr. W. J. Class (*Journal of the American Medical Association*, April 8th) described a micro-organism which he believed to be the specific causative factor of this malady. Klein, in a large number of cases, had isolated a streptococcus considered by him and by a number of French observers to be the cause of scarlet fever. Crajkowski, in 1895, reported that he found, in fifteen cases in which he examined the blood of scarlet-fever patients, a diplococcus present in comparatively small numbers, seldom more than one or two in a microscopic field. This diplococcus did not stain by Gram, and only feebly and then quickly losing its color by any method. Cultures were obtained in bouillon and upon solid media, but not on gelatin. The development was said to be slow, and the colonies resembled small drops of dew, not more than one third to one half of a millimetre in diameter. It was pathogenic for mice, but not for rabbits. Crajkowski, in consequence of the failure of the various careful scientists who took up this work to find a specific germ either in the scales or in the secretions from the throats of scarlet-fever patients, did not assert that the aetiological relation of this diplococcus to scarlet fever had been demonstrated. Dr. Class believed that the fault lay with the culture media employed, as it was a well known fact that some germs were very selective in this respect. After numerous failures, he finally succeeded in finding a culture medium on which he had been able to almost invariably obtain, both from the scales as well as from the throats of scarlet fever patients, the growth of an organism which presented such characteristic features, both in its morphology as well as in its growth, that he

had little hesitancy in asserting it to be the specific germ of scarlet fever.

Morphology.—The diplococcus as ordinarily seen on slides made from fresh cultures resembled a very large gonococcus. This biscuit-shaped appearance was best seen in specimens that had been but lightly stained; in these there was also noted a transverse line running through each half of the organism, giving it the appearance of a tetrad. This appearance was, however, not constant, especially in older cultures, where the organism frequently presented itself as a diplococcus, both segments of which were perfectly globular. The size of the organism also presented a number of variations, but it was always considerably larger than the ordinary pus microbe. The lancet-shaped forms that occurred in the pneumococcus were never met with. Usually, unless in spreading the culture on the slide it was rubbed very hard, these cocci occurred in bunches of from ten to fifty, being united by a large amount of glutinous intercellular substance. Streptococcus forms were occasionally, though rarely, met with, as were also single cocci. They had no capsule and did not show any spores, had no flagellæ, and, examined by the hanging drop, did not show any independent motion.

Staining.—Specimens derived from pure cultures were stained with a number of the aniline stains. With a watery solution of methylene blue very pretty pictures were obtained, especially when only lightly stained; carbol fuchsin also stained them well, and brought out their characteristics. They also stained with Bismarck brown and with Pitfield's flagella stain, but did not stain very deeply, however, with any of the stains mentioned. They were destained by Gram's method, though not to the same extent as the gonococcus, the larger variety of the germ holding the stain somewhat better than the smaller.

Biological Characters.—The culture medium on which this germ grew was prepared as follows: Glycerin agar-agar was made according to the method generally used; to this was added about five per cent. by weight of black garden earth, which had been rendered sterile by intermittent heating. The garden earth was first dried thoroughly, then sifted through a very fine hair sieve until it was reduced to a fine powder, all particles of gravel, sand, etc., being removed; it was then mixed with sufficient bouillon to form a thin paste. This was boiled for an hour, enough sterile bouillon being added from time to time to replace that evaporated by boiling; it was then set in a warm place for a few days to allow the spores found in the earth to develop. It was next boiled for an hour, after which it was again set aside for a few days. This procedure had to be repeated until no growth was developed. It was then added to the agar-agar, which mixture was also boiled for about thirty minutes, and then put aside for a few days to see if any germs developed. Should this be the case, the mixture was again boiled and tested as before. On this medium the scales of a scarlet-fever patient were placed with a sterile platinum loop, and the tubes were put in an incubator, the temperature of which was left at 35° C. Within from forty-eight hours to one week small whitish-gray semitransparent colonies appeared along the tract of inoculation and around the scale. These colonies were isolated at first, but subsequently confluent; their diameter varied somewhat, but in general was about one micromillimetre. On taking up with a platinum needle some of the material of which the colony was composed, it was seen to be glutinous. If the culture

medium was very dry, as happened when the colonies were old, they lost their viscosity and became grayer in color.

On agar-agar and glycerin agar-agar there was no growth. On gelatin the result was also negative. Bouillon was not clouded by the germs, and they apparently did not multiply in this medium. On the blood serum furnished by the health department for the diagnosis of diphtheria there was a growth, but it was much more meagre than on the culture medium described by the author. That the germ had not been noticed when examinations were made with blood serum was probably due to the fact that other germs which were always present on the scales grew so much more abundantly than the diplococcus that their presence was overshadowed, while in the author's medium the diplococcus grew almost to the exclusion of all other organisms. Milk did not appear to be affected by the diplococci, although they apparently multiplied in it. On potato there was no growth.

Pathogenesis.—Rabbits and guinea-pigs were inoculated by subcutaneous injection of a pure culture, by scarification and inoculation of the wounds produced, and by injection into the abdominal cavity, without producing the slightest results. The negative result of the subcutaneous injection showed that the germ was no pus producer, at least not in the species mentioned. Other animals were at present being experimented with by Dr. Class.

The germ described had been cultivated from the scales of about thirty cases of typical scarlatina. It had also been found in the angina of scarlatina, and in cases of angina occurring in persons exposed to scarlet fever in whom no eruption showed, and, lastly, he had found it in the throats of children in a family where one member had typical scarlatina, the children being in a normal condition when the culture was made, but subsequently developing a typical rash, in the scales from which he also cultivated the same germ.

Self-intoxication from the Intestinal Canal.—Dr. Beattie Nesbitt, of Toronto, the editor of the *Dominion Medical Monthly*, has been investigating an important aspect of this subject in the pharmacological laboratory of the Johns Hopkins University. He presents the results of his researches in the January number of the *Journal of Experimental Medicine*, in an article entitled *On the Presence of Choline and Neurine in the Intestinal Canal during its Complete Obstruction*.

Dr. Nesbitt's experiments lead him to believe that complete occlusion of the small intestine at its lower end will give rise to the occurrence of choline, neurine, and perhaps other bases, provided the food taken contains any considerable quantity of lecithin. It is not improbable, he thinks, that still other poisons are formed by bacterial action from other constituents of the food in cases of intestinal obstruction. While choline would have to be absorbed in relatively large amounts to exert a marked toxic action in human beings, he says, it is different with neurine, which is many times more intense in its action, and must be classed with the exceedingly active poisons. It has been shown both by the experiments of Schmidt and Weiss, Dr. Nesbitt remarks, and also by those recorded in this paper, that the poisonous neurine may be formed from choline by bacteria. In its physiological action neurine agrees closely with muscarine; and especially to be noted is its paralytic action on the heart and its power to increase

the intestinal movements to such an extent that continual evacuations occur. Whether the ptomaine which was found by him is poisonous he can not yet say. It must be considered proved, however, he thinks, that highly toxic substances may arise in the intestinal canal during its complete occlusion. The method of treating cases of intestinal obstruction, before surgical means are resorted to—namely, by washing out the stomach and as much of the gut as possible—often reduces the violent peristalsis, and this is due, perhaps, to the removal of substances out of which irritating and toxic products are formed by bacteria.

In conclusion, Dr. Nesbitt remarks that our knowledge of the fate of lecithin in the digestive canal under normal conditions is very deficient. The assumption that it is saponified by the fat-splitting enzyme of the pancreatic juice, thus yielding choline, glycerophosphoric acid, and fatty acids, rests on the work of Bokai in 1877, in which, as that investigator himself admits, bacterial action was not excluded. This omission throws grave doubts on the results. If the assumption of Bokai is correct, caution must be observed in the use of some foods that have been considered most nutritious and healthful; for instance, the ingestion of a meal made up largely of eggs would hardly be without danger, because of the poisonous action of the large quantity of choline liberated from the lecithin and the probability of the formation of the highly poisonous neurine.

A Case of Family Periodic Paralysis.—At the recent meeting of the Association of American Physicians Dr. J. K. Mitchell (*Medical News*, May 13th) reported the case of a boy, aged eighteen years, who had attacks of paralysis occurring at frequent intervals. He might retire perfectly well, and yet awake in the morning helpless, paralyzed from head to foot, with total abolition of skin, muscle, and tendon reflexes, loss of faradaic and galvanic contractility, unchanged sensibility, and unimpaired mind and speech. Five cases of a similar nature had been seen in his mother's family. The boy had been kept in the hospital occasionally for periods of six months, so that careful blood examinations and a careful study of the body excretions could be made in order to determine if possible the presence of toxins. While this had not been entirely successful, Dr. Mitchell was not inclined to look upon the case as purely hysterical, but rather believed it to be due to self-intoxication.

Proceedings of Societies.

SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

Meeting of February 8, 1899.

The President, Dr. WILLIAM L. STOWELL, in the Chair.

The Doctor Outside of Medicine.—The President delivered an address on this subject. (See page 765.)

Syphilis Affecting Both Eyes.—Dr. H. S. OBERHEIMER presented the following case: A young man, twenty-one years of age, came to the speaker two or three weeks ago with the following history: His left eye had received a blow from a baseball some eight years ago, which injury had rendered the eye entirely

useless, according to the patient's notion. His right eye on New Year's day had been struck on rising from a stooping posture, at the temple, not at the eye itself. After this "bump" he had noticed that his right eye was not as good as it had been. The speaker had examined the eye, and the examination of it put quite a different phase upon the case and the preconceived notion of it, after hearing the history. In the left eye, the one which was said to have been struck with the baseball eight years before, he had found a very marked picture of a retrogressive neuroretinitis. The nerve was partially atrophied, but around the macular region there was a beautiful deposit of pigment with the macula itself showing almost as brilliantly in the middle of this as it did in embolism of the artery. In the right eye the picture was different, but very much the picture that the other one might have presented if it had been seen earlier. In the cornea of the right eye there was a distinct marking of what was called descemetitis. It was a series of opacities, as if a pepper box had been spilt on the posterior portion of the cornea. It was a distinctive symptom of serous iritis. The vitreous humor was filled with all sorts of opacities, one of a horse-shoe shape, and a number of smaller ones and floating opacities. In the fundus there was an exudation into and under the retina, showing in its neighborhood some of the pigment deposits similar to those shown in the left eye; in short, a process in the retina, and perhaps more or less in the choroid, which had come to nearly its end in the left eye, was to be seen in the right in a more recent stage. The etiology was this: There had been a primary lesion about a year before, and he had gone promptly to a physician, frightened about it; there was a hard, painless lump which the doctor had burned out. The patient had continued to go to his physician again and again, being nervous over it, but finally the doctor had said that there was nothing to be apprehended, and that he need not come any more. The case was presented on account of the interesting picture that the eyes presented to those who used the ophthalmoscope, and also as showing another one of the cases in which the primary lesion had been destroyed, in which, in spite of the fact that this had occurred over a year ago and there had been no secondary symptoms, there was a distinct characteristic picture of syphilis of the eye. There was no lesion in the skin, but there was a slight enlargement of the glands, which moved freely, and which the author had seen more pronounced in perfectly healthy persons; there was no history of any eruption; there was no history of any pains or aches, or any lesions in the mouth or throat, which one was apt to inquire for.

Dr. A. T. MIZZY said that the picture in the left eye was certainly a very characteristic and beautiful one for that condition. The case was one of those objective conditions that could be seen with the mirror; otherwise it needed the history and progress under treatment, such as the doctor described, to make us sure of our ground. In the speaker's experience he had never met with such a pronounced eye picture without plenty of gross lesions in other situations, notably pharyngeal, or the usual history of a primary stage.

Dr. J. B. BUSTEN said, in regard to the absence of secondary symptoms, that this was not uncommon in the disease of syphilis, for he had often found a patient with a typical sclerosis and eruptions, without further symptoms, go on for the rest of his life and die of some other disease. One would have an eruption and nothing

else; another would have a sclerosis and mucous patches, and nothing else for years, and then again a man would have a sclerosis, but not the mucous patches, and he would go on, and years later have a syphilitic disease of the ear, or, in the same way, a syphilitic disease of the eye.

Dr. GEORGE T. JACKSON said that he agreed with Dr. Oppenheimer in his statement that he had often found the inguinal and other glands enlarged in perfectly healthy people. He thought too much stress was laid on the enlargement of the glands as a sign of syphilis. We often saw patients with syphilis in whom the glands were apparently not enlarged at all, at least none could be found. He regarded enlargement of the glands as a corroborative, but by no means a positive sign of syphilis.

Dr. OPPENHEIMER said that the case was interesting to him because it surprised him. To begin with, the boy had given a history of traumatism when there had not been any trace of it, but the blood-vessels in the right eye had shown a distinct affection. The left eye had shown the pigmentation beautifully, and also some affection of the vessels. That this disease should exist without either the outer covering or the inner covering of the patient's—i. e., the skin or mucous membranes—being affected, and again that there should be a serous iritis, was rather unusual, and he thought it might be of interest to Charity Hospital graduates to notice that the primary chancre had been destroyed, and yet it had made no difference in the advance of the disease. He thought the patient would recover; he probably would not have perfect sight in the left eye, because that process had run its course and there was more or less atrophy of the nerve; but the right eye would probably recover from the trouble in the vitreous and in the retina.

Strangulated Hernia and Undescended Testicle.—Dr. BISSELL presented a specimen, taken from a man fifty-eight years old, of a strangulated hernia with an undescended testicle in the inguinal canal.

Foreign Body in the Thumb.—Dr. BISSELL showed a Röntgen picture of a girl's hand with a needle in the thumb close to the bone. The patient had been operated upon and the needle had not been found; cellulitis had followed, and a few days later a Röntgen picture had been made, and by means of the plate the needle had been taken out with one slight incision.

Rupture of the Heart.—Dr. NEWTON presented a heart with the following history: F. M., single, American; carpenter; aged twenty-eight years. On September 19th he was riding a bicycle rapidly when his front wheel struck a piece of rubber and canvas hose four inches in diameter. This hose was lying on the ground and was filled with water, which it was conveying under considerable pressure from a hydrant to a water cart. As to precisely what happened after the collision with the hose the accounts of the two or three eyewitnesses to the accident differ somewhat. The wheel, however, was broken at or near the junction of the fork and the head, and the man was thrown a foot or two in the air, falling heavily to the ground. He got up and staggered toward the water cart, holding on to his left side. He then sank upon the ground and became nearly but not quite unconscious, at the same time groaning and writhing with pain and showing a tendency to curl himself up, rolling over on his left side. Dr. Wilson, of Bloomfield, was brought, who thought that the patient was suffering from concussion. A hypo-

dermic of brandy was given, and the man was directed to be taken to the Mountainside Hospital.

Before reaching the hospital he revived a little, so that he could give his name and residence. He was still helpless and in great pain. He was brought into the dispensary and placed upon the examination table. His pulse was 78, regular, and moderately strong. He asked for water two or three times, but was scarcely able to swallow any of it. He would throw himself about as though struggling for air, and was inclined to roll over toward the left side. He did not seem to the attendants like a man fatally hurt, but rather like one who had been badly shaken up by a severe fall and who had severe colicky pains. The surgeon on duty, who happened to be Dr. Newton, was summoned, but before his arrival the man quietly died. There had been no vomiting, and the bladder had not been emptied. There had been no convulsions or spitting of blood. Dr. Washington, the county physician, was notified, and on the following day permitted a partial autopsy. The body was that of a well-nourished, muscular young man. Except two or three unimportant abrasions on the legs and a small punched-out semicircular mark on the skin over the sixth rib on the left side, no external injuries were noted. An inch or two inside of the semicircular mark just referred to was a slight depression of the surface, and pressure over this elicited the fact that the sixth costal cartilage had been fractured. On opening the chest nothing abnormal was observed, except the fracture, as noted above, and some laceration of the neighboring intercostal muscles. The pleura and pericardium were intact. The latter, however, appeared somewhat distended, and on opening it from eight to ten ounces of dark clotted blood were observed between its pericardial and epicardial layers. When the heart was lifted it was observed to be about normal in size, perhaps a little hypertrophied; the walls were relaxed and the cavities contained a few post-mortem clots. A rather large transverse rent, with everted edges, was noted at the apex of the right ventricle. The measurements of the rent were an inch and a half externally and three eighths of an inch internally. The internal opening was immediately contiguous to the interventricular septum.

Dr. Newton said that he thought there was no doubt that the tear had been made from without inward; that the heart had been struck in systole by the broken end of the sixth costal cartilage, which had pushed the pericardium before it and ruptured the ventricular wall at its thinnest portion without tearing the pericardium.

Dr. MANGES opposed this view of the receipt of the injury, maintaining that the probabilities were strongly in favor of a rupture from within outward.

Dr. RUFF agreed with the first speaker, and thought that as the external wound was so much larger than the internal, and the history pointed so strongly toward direct injury, there was little doubt that the rent had occurred as Dr. Newton suggested.

Dr. NEWTON called attention to the fact that the heart was of about normal size, and possibly a little hypertrophied; that the muscle fibres were apparently quite healthy; that the subject was an athletic young man in excellent physical condition, and an experienced bicycle rider. There was no likelihood, therefore, of a spontaneous rupture, as the cardiac structures were in an excellent condition, and, as to a rupture from strain, he doubted if it ever occurred through healthy ventricular walls.

He regretted that he had not had time to investigate this case thoroughly or to look up the literature of the subject, but he intended to do so, and would report later to this society or some other in reference to the matter.

Book Notices.

The Pathology and Treatment of Sexual Impotence.

By VICTOR G. VECKI, M. D. From the Author's Second German Edition, revised and rewritten. Philadelphia: W. B. Saunders, 1899. Pp. 11 to 291. [Price, \$2.]

THIS work should prove of great interest and value to the practitioner, for, as the author says in his introduction, "it must be admitted that the subject has never received the attention its preeminent importance deserves. The world over, it seems to be considered the proper thing to treat the affair with supercilious nonchalance." Yet reflection will surely make it clear that a subject which is the natural basis of love, the foundation of the home and the family, which is intimately associated with the character and general appreciation of life, and with the mental, moral, and physical well-being of the entire organism, can not be so universally neglected without evil consequences as far reaching as the sexual functions themselves.

How often is not suicide the result, direct or indirect, of impotence? Strong as the statement is, we feel that it is not altogether wide of the mark when the author says: "I venture to assert that in many cases it is a better deed to restore to an impotent man the powers, so precious to every individual, than to preserve a dangerously sick person from death, for in many cases death is preferable to impotence."

The work deals systematically and in detail with the anatomy of the male genital organs and the physiology of the sexual act. The author then discusses the etiology of impotence, and its forms, which he subdivides into five classes—viz.: 1. That due to congenital malformations and defects of the sexual organs. 2. That due to acquired defects. 3. Consecutive impotence. 4. That due to inherited predisposition. 5. Neurasthenic impotence. The diagnosis, prognosis, and prophylaxis are next treated of in separate chapters, and finally the subject of treatment is dealt with in a most exhaustive manner in all its phases. This section is especially "up to date."

The author expresses what seems to us very sound views on the knowledge to be imparted to the adolescent and on the manner of its imparting and the limitations thereof. The comparison of the difference between the evil effects of masturbation (which, however, the author continuously terms onanism, the proper name for what he elsewhere refers to as "frauding" in the sexual relations) and excessive venery is exceedingly well drawn.

There is much that will not be agreed to by many when the author ventures into the field of opinion, and we make bold to suggest that sarcastic or cynical remarks about people who from training or other propensities are unable to lay aside a dominant influence and look at matters in the dispassionate light of cold facts, will militate against the author's end, where a judicious silence would have aided it. But of the inestimable

value of the actual practical part of the work as a treatise for the guidance of the practitioner in the etiology, pathology, and treatment of one of the most far-reaching and distress-producing ailments in the world, it seems to us there can be but one opinion.

BOOKS, ETC., RECEIVED.

A Text-book of Mental Diseases. With Special Reference to the Pathological Aspects of Insanity. By W. Bevan Lewis, L. R. C. P. (Lond.), M. R. C. S. (Eng.), Medical Director, West Riding Asylum, Wakefield, etc. Second Edition, thoroughly revised, enlarged, and in part rewritten. With Illustrations in the Text, Charts, and Twenty-six Lithographed Plates. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. xxvi-609. [Price, \$7.]

Atlas of Diseases of the Skin. Including an Epitome of Pathology and Treatment. By Professor Dr. Franz Mraček, of Vienna. Authorized Translation from the German. Edited by Henry W. Stelwagon, M. D., Ph. D., Clinical Professor of Dermatology, Jefferson Medical College, Philadelphia. With Sixty-three Colored Plates and Thirty-nine Full-page Half-tone Illustrations. Philadelphia: W. B. Saunders, 1899. Pp. 7 to 199. [Price, \$3.50.]

The Study of the Hand for Indications of Local and General Disease. By Edward Blake, M. D., Member of the Royal College of Surgeons, etc. Second Edition. London: Henry J. Glaisier. New York: G. P. Putnam's Sons, 1899. Pp. xvi-135. [Price, 5s.]

Clinical Lectures on Neurasthenia. By Thomas D. Savill, M. D., Physician to the West-End Hospital for Diseases of the Nervous System, London, etc. London: Henry J. Glaisier, 1899. Pp. xv-144. [Price, 3s. 6d.]

Massage and the Original Swedish Movements. Their Application to Various Diseases of the Body. By Kurre W. Ostrom, of the Royal University of Upsala, Sweden. Fourth Edition, revised and enlarged. With One Hundred and Five Illustrations. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. viii-9 to 168. [Price, \$1.]

Vital Science Based upon Life's Great Law. The Analogue of Gravitation. Agnosticism Refuted. By Robert Walter, M. D. Philadelphia: J. B. Lippincott Company, 1899. Pp. xix-17 to 319. [Price, \$1.50.]

Bad-Nauheim. Its Springs and their Uses, with Useful Local Information and a Guide to the Environs. By J. Groedel, M. D., Medicinalrat, Physician in Bad-Nauheim. Second Edition. From the German Guide to Bad-Nauheim by O. Weiss and J. Groedel. Friedberg and Bad-Nauheim: Carl Bindernagel, 1899. Pp. viii-176.

The Healthfulness of Sunshine.—*Practical Medicine* for May quotes the following remarks of a "California doctor," which seem to us worthy of reproduction:

"It is astonishing how few people there are who properly estimate the hygienic value of the sun's rays. A valuable lesson on this point may be learned by observing the lower animals, none of whom ever neglect an opportunity to bask in the sun. And the nearer man approaches to his primitive condition the more he is

inclined to follow the example of the animals. It is a natural instinct which civilization has partially destroyed in the human race. The effect of sunshine is not merely thermal; its rays have chemical and electrical functions. It is more than possible that sunshine produces vibrations and changes of particles in the deeper tissues of the body as effective as those of electricity. Many know by experience that the relief it affords to wearing pain, neuralgia and inflammatory, is more effective and lasting than that of any application whatever. Those who have face-ache should prove it for themselves, sitting in a sunny window where the warmth falls full on the cheek. For nervous disability and insomnia the treatment of all others is rest in sunshine."

Official Report on the Food Supply in the Philippines.—The *Army and Navy Journal* for May 13th says: "A report has been received by the surgeon-general of the army from Major H. W. Cardwell, surgeon of the First Division of the Eighth Army Corps, giving an account of the food supply and its preparations in the Philippines. Dr. Cardwell states that absolutely no fault is to be found with the supply of food or lack of it. Great ingenuity has been exercised by the various companies in the erection of brick and stone ovens in the courtyard of Cuartel for use in roasting and bread-making. The tops of many of these ovens are being used as huge stoves. The report concludes as follows: 'The issue of fresh beef has been sufficient, and its quality is first class. Companies who do not bake their own bread buy from those who do, or from the regimental bakers, and the quality is equal to the best American city bakeries. Potatoes and onions, fresh, with the usual canned goods from the commissary, and such green produce as can be obtained from the markets supply an ample vegetable ration. The issue of rice in additional quantities by the commissary is appreciated, and, strange to say, those most liable to complain that the quantity is insufficient are newly arrived organizations. I find that many, especially among the officers, who have been there for six months or more crave and eat as much meat as they did in the United States.'"

"Fake" Medical Statements in the Lay Press.—We quote the following from the *Medical Examiner* for May: "These news-mongers do not hesitate to fake in medical matters. As we have had occasion to remark in a former editorial, the most improbable and miraculous instances of medical skill and surgical procedures are minutely described without the shadow of a foundation. The developments of science and art are so wonderful in these days that fake writers take advantage of the fact and palm off almost anything of a marvelous nature upon the incredulous as truth. To-day it is not safe to either believe or deny any statement of this class offhand, but the instances are too numerous of scientific pervariation by false purveyors of news to permit the thing to go on much longer without a solemn protest. Newspapers are becoming the objects of discredit; their statements can not be believed as in former times. To follow the so-called news, scientific or otherwise, with any degree of comfort, or, as they say in mercantile life, 'E. O. E.?' that is, errors and omissions excepted, is almost impossible. It is time to ask the public to look into the matter, or the press in America will fall into disrepute. Willful lying, when detected in publications which are depended upon by our people for au-

thentic information upon affairs, should be punished in some way. If it is the intention or the business of such publications to deceive, they should so state upon their title-pages, and not speak seeming truth when truth is not to be found in them. It is practically the case now that no statement made can be believed without verification. Public morality is rapidly being undermined, and faith in current literature is fast diminishing; false notions regarding medical matters, which tend to bring the profession into contempt, are being inculcated by anonymous and irresponsible newspaper writers. This last idea may be confirmed in the reading of almost any edition of the Sunday newspaper. It is about time for medical men to look into this matter."

An Act of Medical Heroism.—The *Lancet* for May 13th records the following instance of medical heroism: A man swallowed some phosphorus paste in beer. The police sent for Mr. R. J. Burns, a surgeon of Sunderland, who promptly attended, bringing a stomach pump with him. Unfortunately, the pump was out of order, whereupon the surgeon passed the tube and sucked out the poisonous contents of the man's stomach with his mouth. Apart from the personal danger attendant on such a proceeding its repulsiveness is a condition adding materially to the nobility of the doctor's undertaking. Unfortunately, the heroic act was unsuccessful, for the patient died, while the doctor himself suffered from serious, though happily not fatal, symptoms of poisoning. There are heroes everywhere and in all walks of life; but this devotion, not only regardless of danger but unstimulated by the suggestion of romance, and under circumstances peculiarly repulsive to human sensibility, and in our judgment in excess of what duty absolutely demands, belongs to a field of opportunities especially common and incidental to the medical profession, which may congratulate itself on the possession of members like Mr. Burns, who rise to the opportunity.

The Massachusetts Medical Society.—The one hundred and eighteenth annual meeting will be held in Boston on Tuesday and Wednesday, June 13th and 14th, under the presidency of Dr. Edwin B. Harvey, of Westboro. The section meetings will be held in the Mechanic Building on Tuesday. The programme for the Section in Medicine, under the chairmanship of Dr. C. F. Folsom, of Boston, includes the following papers: The Clinical Importance of a Knowledge of the Size of the Heart, by Dr. F. H. Williams, of Boston; The Diagnostic and Prognostic Value of the Pulse, by Dr. Henry Jackson, of Boston; The Prognosis of Nephritis: A Study of Five Hundred Cases, by Dr. R. C. Cabot, of Boston; and The Role of the Staphylococcus in Skin Diseases, by Dr. C. J. White, of Boston. The order for the Section in Surgery, under the chairmanship of Dr. E. H. Bradford, of Boston, is as follows: Intus-usception, by Dr. J. C. Munro; The Completed History of a Case of Gastrocnemius. Remarks upon the Surgery of Gastric Cancer, by Dr. M. H. Richardson, of Boston; and A Lantern-slide Demonstration of the Dissemination of Chancres, by Dr. W. T. Councilman, of Boston. The Shattuck Lecture will be given on Tuesday by Dr. James J. Putnam, of Boston, on the subject of Mental Therapeutics from the Standpoints of the Physician and the Psychologist. The general meeting will be held in the Mechanic Building on Wednesday, at which the following papers will be read: Improvements in Army Medical Science, suggested by Experience in

the Late War, by Dr. W. H. Devine, Lieutenant-Colonel and Medical Director, Second Brigade, M. V. M.; A Report of the Blood Examinations in Typhoid Fever and in the Malarial Fevers, by Dr. J. J. Curry, Acting Assistant Surgeon, U. S. A.; A Hospital Clearing House, by Dr. C. J. Blake, of Boston; The Demonstration of Parasites in the Blood and Tissues in Malaria, by Dr. J. H. Wright, of Boston; and The Methods of Conducting Volunteer Aid in Foreign Territory, by Dr. E. G. Brackett, of Boston. The annual discourse will be delivered at noon by Dr. Edward H. Bradford, of Boston.

Appendicular Inflammation at Nineteen Months.—Dr. R. Millon (*Archives de médecine des enfants*, May) records the case of a female infant nineteen months old on whom he operated successfully for removal of the appendix.

An Indian Prince Vice-president of the Indian Medical Association.—The *Indian Medical Record* for April 26th says that his Highness Sir Bhagvat Singhjee Jareja, G. C. I. E. Thakore Saheb, of Gondal, is the most enlightened and most scientifically advanced of all the princes of India. He qualified as a barrister-at-law in 1886, taking the degree of LL. D. during that year. He then commenced the study of medicine in the University of Edinburgh, and graduated with honors as M. B., C. M., in 1892. In the same year he received the degree of D. C. L. at the University of Oxford, and the M. R. C. P. of Edinburgh. In 1895 he qualified for and was admitted to the F. R. C. P. of Edinburgh, and in the same year graduated as M. D. in the Edinburgh University by a thesis that was most creditably commented on. Sir Bhagvat Singhjee is the author of that well-known classical work *The History of Aryan Medicine*. The Indian Medical Association, says the *Record*, may well be proud to have a gentleman of such distinguished scientific attainments, and a nobleman possessed of so many brilliant qualifications, as its nominal head.

The University and Bellevue Hospital Medical College held its commencement exercises on Tuesday evening, May 16th, in the Metropolitan Opera House. The graduating class consisted of a hundred and sixty-two gentlemen.

More Verses on the Doctor.—The *Australasian Medical Gazette* for April 20th publishes the following:

DOCTOR.

BY A DYSPEPTIC G. P.

(With apologies to R. K.)

I entered the profession, like other men, to live;
I've found how very few and rare the prizes it can give.
I've striven long from ill and death my fellow men to guard,
And many kicks, but ha'pence scant, received as my reward.
For it's Doctor this, and Doctor that, and "Doctor's gross mistakes,"
But it's "Run and fetch the doctor," when the little finger aches.
When your little finger aches, my friends, your little finger aches;
Oh, it's "Run and fetch the doctor" when your little finger aches.

We bolt our meals, we scamp our sleep, we little know of rest;

Through four and twenty hours we wait the club patient's behest.

You ring us up at midnight, you rush us all the day,
You wear our souls and bodies out, and then refuse to pay.

For it's Doctor this, and Doctor that, and "What a monstrous bill!"

But it's "Doctor, won't you save her?" when the only child is ill—

When your only child is ill, my friends, your only child is ill;

Oh, it's "Save her, never mind the cost!" when the only child is ill.

We face the plague and pestilence, greet danger with a laugh;

We win our V. C.'s day by day, and get repaid in chaff.
The very depths of human life, the foul and mean we scan;

But bitterest of all we find the ingratitude of man.

Oh, it's Doctor this, and Doctor that, and "lazy, careless brute!"

But it's "Noblest of professions" when the pains begin to shoot—

When your pains begin to shoot, my friends, your pains begin to shoot;

It's "Noblest of professions" when your pains begin to shoot.

You spend your time in idle talk, and pass the careless lie—

How that d—d doctor messed your case, and made you nearly die.

And everywhere you seek to do him all the harm you can,

And vile traducer though you be, pose as an honest man.

For it's Doctor this, and Doctor that, it's charlatan and quack;

But it's "Skillfullest physician" when you're laid upon your back—

When you're laid upon your back, my friends, you're laid upon your back;

Oh, it's "Skillfullest physician" when you're laid upon your back.

The papers rave about our mission, which they call divine,

Or deprecate our selfishness because we dare combine.

The manna drops from heaven, they think, to feed us and our wives;

Our business not to save our own, but only other lives.

For it's "Sawbones this," and "Butcher that," and any other taunt;

But in the Valley of the Shadow it's the doctor that you want—

It's the doctor that you want, my friends, it's the doctor that you want;

In the Valley of the Shadow it's the doctor that you want.

The Berlin Tuberculosis Congress was opened on Wednesday, May 24th, in the presence of its patroness the Empress Augusta Victoria.

The Principles on which the Legislative Right to Control the Practice of Medicine is Based.—*The Journal of the American Medical Association* for April 29th

says that in the recently reported case of the regular State Board of Medical Examiners *vs.* Fowler, the supreme court of Louisiana lays down a number of propositions of general interest. It holds that whenever the pursuit of any particular occupation or profession requires, for the protection of the lives or health of the general public, skill, knowledge, and other personal attributes or characteristics in the person pursuing it, the general assembly has the power and authority to have recourse to proper measures to insure that none but persons possessing these qualifications shall pursue it, and that a statute to that effect is not open to attack as depriving citizens of their right to earn a living. The right to practise medicine, it declares, is not an absolute natural right, but a right or privilege to be exercised under conditions and limitations regulated by legislative authority. Since the general assembly has the authority to require, as a condition precedent to the right or privilege of any one to practise medicine in Louisiana, that he should be subjected, before doing so, to an examination as to his qualifications, and be found and declared worthy and qualified, it has also the right to select the particular agency to whom should be delegated that duty. Courts can not control that selection. A statute creating a board of medical examiners, to be composed of physicians recommended for appointment from lists to be furnished by the Louisiana Medical Society and the Hahnemann State Medical Society, to be appointed by the governor on such recommendation, is not open to attack as discriminating in favor of the regular and homeopathic schools against the eclectic school of medicine. No constitutional right is given to particular individuals entertaining peculiar theories of medicine to group themselves together and, calling themselves a special school of medicine under a selected name, to insist that they be recognized and dealt with as such. The action of the medical board of examiners is not conclusive, but is subject to correction in case of abuse. The recognition by the constituted authorities of another State that a person was properly qualified to practise medicine, and that the medical college whose diploma he presents as evidence of the fact was a medical college in good standing, does not carry with it a vested right in the party to practise medicine in Louisiana. Each State acts independently of the other in this matter. Nor is a person who has been practising medicine as a physician for a number of years, without objection, exempt from complying with legislation of a later date, making it a condition precedent to any one's practising medicine that he should have been examined by a medical examining board found to have the qualifications required by law for so doing.

The American Electro-therapeutic Association will hold its ninth annual meeting in Washington on September 19th, 20th, and 21st under the presidency of Dr. F. B. Bishop, of Washington.

Death of Dr. Büchner.—We learn from *Science* for May 12th of the death of Dr. Friedrich Karl Christian Ludwig Büchner, who was born in 1824, and after practising medicine became docent at Tübingen, from which position he was dismissed in consequence of the materialistic doctrines in his book on *Matter and Force*, published in 1865. Thereafter he practised medicine at Darmstadt. Büchner was well known for his series of popular works on physical science and the theory of evolution, as well as for numerous contributions to physiology, pathology, and other sciences.

Original Communications.

THE PRESIDENT'S ANNUAL ADDRESS
TO
THE AMERICAN MEDICAL ASSOCIATION.

By JOSEPH M. MATHEWS, M. D.,
LOUISVILLE.

MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION, LADIES, AND GENTLEMEN: In assuming the duties of the presiding officer of this association, I must confess that it is with a feeling of great diffidence. For many years I sat at the feet of the masters in medicine, as they were wont to assemble at their annual meeting, and was content to listen only to their wise counsels, to emulate as far as I could their example, and to profit by the words of wisdom which fell from their lips. When I reflect upon the names of my predecessors who have occupied this chair, their great achievements in medicine, the high rank to which they attained, and the good which they accomplished, it is no wonder that I assume the rôle with some trepidation. You will therefore permit me to offer you my very sincere thanks for the honor which you have conferred upon me.

In assuming the duties as your chairman, I hope to be just to all, and if at any time my decisions should appear otherwise, please attribute it to my head rather than my heart. It pains me to look over this great body and recognize the fact not only that many of its most prominent members in the past are absent, but also that the majority of those who have served you as president have also gone to their eternal home. Let their departure remind us that we, too, must soon lay aside our armor and join the silent majority. This thought brings me to consider for a moment:

OUR NATIONAL BODY: ITS PURPOSES AND DESTINY.
—I imagine that when the father of this association, the Nestor of American medicine, called around him a few devoted friends, accomplished physicians and surgeons, and effected an organization to be known as the American Medical Association, the first thought which filled their minds was the unification of the profession which they loved so dearly. It was their desire, no doubt, to bring together each year the men who were laboring earnestly and honestly for the elevation of the profession, that they in conclave could impart to each other the advance that each succeeding year had brought forth in their chosen calling, and this done in order that the sick and afflicted could be profited thereby.

Sacrifices and great personal discomfort were endured by them to obtain the good; but what splendid results were accomplished by their efforts is evidenced in the assembling of this great body here to-day. I opine, too, that anything that partook of the nature of

jealousy, unfairness, or politics was deprecated by them, but, to the contrary, they desired that peace and goodwill should always obtain. What could be more beautiful than the fruition of this hope? How grand the thought that here in the mother society men of all grades, so far as education and accomplishments are concerned, be they great or small, poor or rich, the rank and file of the profession, can meet on common ground and exchange views for the benefit of suffering humanity! Some must be teachers or instructors, others listeners; they each in their way contribute their mite. It may be that some member from a far-off and sparsely settled country has heard some truth by the application of which a life may be saved, or in return he can give an experience which may prove of incalculable benefit to his more fortunate brother. Let me impress upon you, then, that no class legislation should be indulged in by this body. Let it not be said of us that we rule without reason, or that we are a set of politicians trying to secure benefit for the few against the many, or for the many against the few, for in no wise are we a legislative body. In lieu of all this, let us receive with open arms all who represent honesty and fair dealing and entertain an earnest desire to elevate the standard of the medical profession and of this association. Let no wrangling come into our midst, but rather let peace and harmony prevail, with love to one another, as becomes gentlemen.

SHALL WE HAVE A LOCAL HABITATION?—It is to be seriously questioned whether this association, so numerically great as it is destined to be, or in truth is now, profits in any manner by its migration each year to distant parts of the Union. It can not be denied that a mistake has been made in the past in going to cities too small to entertain it. It certainly adds no dignity to this distinguished body to be thus traveling about, not to speak of the inconvenience occasioned to the majority of its members by so doing. Nor is it right or proper to impose upon a local profession the expense and trouble that it takes to entertain it. If the members will give the subject careful thought and consideration, I believe that they will come to the conclusion that the association should have a local habitation. The natural question would then be, Where could such habitation be found? In the selection of the same, many things would have to be considered. A city within easy reach, which offered the most attractive advantages. Of all, the city of Washington is the best suited. The capital of the nation, it has advantages that no other place can offer. With its great free libraries, it is the seat of learning; its magnificent government buildings, its natural beauty, its select society, its two houses of congress, the rendezvous of foreign representatives and diplomats, the home of the medical departments of the government, army, navy, and Marine Hospital corps. Then, too, the idea is not far fetched that the gov-

ernment, liberal always, would at some time lend the association a helping hand in the way of securing a suitable building in which to hold its meetings and of which to become the owner. Again, it would be in touch with the legislative department of the government, and it can readily be seen of what value this would be in securing much-needed reforms in a medical way. The *Journal* would here find the most suitable of all abodes: an atmosphere of refinement, education, and wealth. Its editor would all the time be on the alert, and much profit would come to the *Journal* from such surroundings and associations. I beg of you to give this matter your most serious consideration.

IMPORTANCE OF ATTENDING THE LAST DAY'S SESSION.—I desire to call your attention to the importance of attending the general session on the last day of the meeting. Business of the very greatest importance always comes up for consideration on that day, and, strange to say, often there is scarcely a quorum present. At the meeting at Denver last year fewer than fifty members were in attendance on the last day of the meeting. If, therefore, resolutions are rushed through on that day which displease you, it is your own fault. Besides, if the business transacted on that day comes up for consideration at the following annual meeting, it takes up time which it has no right to. Please, therefore, see to it that nothing interferes with your attendance on that day.

CLINICS, DINNERS, ETC.—It has been a noticeable fact for a long time that the clinics which are held each year during the meeting of the association, by the local profession of the city in which it happens to meet, very materially decrease the attendance at both the general sessions and those of the various sections. This should not be, and it is the duty of the proper officials of this association to deprecate the holding of such clinics. Time and again many of the very best men of the association have been kept away half a day, and often a whole day, from the meeting, when their counsel and presence were much needed at the different sections or at the meeting in general session. Need I remind you that absence of the same kind and duration is often occasioned by dinners to which the members are kindly invited? This can easily be obviated.

THE JOURNAL.—It is my painful duty to announce to you the death of Dr. John B. Hamilton, editor of the *Journal* of the association. This association never had a truer friend than he. Possessed of a clear-cut individuality, he was always outspoken, and what he did he at least believed to be for the best. We shall miss his wise counsel in our deliberations. He made a most excellent editor of the *Journal*, and by his efforts it was brought up to the high standard which it occupies to-day. The board of trustees of the *Journal*, after careful consideration and deliberation, has selected Dr. George H. Simmons to succeed Dr. Hamilton as editor. You are to be congratulated upon this wise selection. Dr.

Simmons is not an experiment, for he has won his laurels in medical journalism, and already stands among his editorial friends as the peer of any. Having come up from the ranks in journalism, he is acquainted with every detail, and that he will make a good editor goes without the saying.

The Management of the Journal.—I trust that it will not be considered out of place if I make a suggestion or two in regard to the management of the *Journal*. It has been frequently urged that much appears in it that should be expurgated. In other words, that a censorship should be established and many articles withheld from publication. I desire to dissent from this sentiment entirely and unequivocally. The *Journal* is simply the mouthpiece of the association, and if one single paper read before this body is to be refused publication, then you have violated your pledge and obligation. Any member has the inalienable right to disagree with the sentiment of any paper, and the editor is in no wise responsible for said sentiment. If a paper is good enough to be read before any section in this association, it is good enough to be published in the *Journal*. If any action is taken, it should be by the chairman of the section before which the paper is to be read, saying to the reader that his paper does not come up to the standard. But who will assume this responsibility? and who is to judge the judges? May it not be that a paper, although couched in bad English, might contain matter of real merit? Many articles, too, with high-sounding titles and verbiage beyond the comprehension of man may contain but little that is of worth, although written in perfect English, with deductions that would puzzle a philosopher, and which contain illustrations that would do credit to *Puck*. By all means let the editor improve the *Journal* in any way that he deems proper, but let every paper read before this association or its sections be published in the *Journal*. Let the reader select the wheat from the chaff, the good from the bad. In connection with the business interests of the *Journal*, I beg to make the following suggestion: Let a suitable man be selected, preferably a doctor, to travel in its interest, thereby increasing the membership of the association; this agent, secretary, assistant secretary, or whatever you may choose to call him, to solicit subscriptions for the *Journal* and encourage membership. He should visit the meeting of each State, district, and county society, besides calling on individual members of the profession. Of course, only those who are indorsed by accepted or recognized organizations can become members of this association. There are many hundreds of worthy physicians in the United States who would readily join the mother society if properly approached. Many, very many of them are ignorant of the manner of becoming members. It may be urged that the salary necessary to secure such an agent would be too large to justify the employment of such. In refutation I would urge that by such individual solicitation

many more would be added to the membership than would be necessary to pay said salary, and they would become permanent members. It can be said, especially to young men, that the mere wearing of the button of the association adds dignity and confidence. Then, too, it can truthfully be asserted that the *Journal* alone is worth more than the sum paid for membership. By this means I am sure that the treasury would be so increased as to enable the *Journal* to be the peer of any published. Besides, our ranks would be so increased as to make this association not only the largest but the most important in all the world.

THE SECRETARYSHIP.—For several years there has been a heated debate, if not wrangle, at each annual meeting, in general session, over the secretaryship. This is both unseemly and undignified, and is much to be deplored. It seems to me that there is an easy solution to this matter. Let the editor of your *Journal* be the secretary of the association. The board of trustees has wisely insisted that he devote his whole time to the *Journal*. It does, therefore, appear that the secretaryship should be one of his duties. By so acting he is brought into a closer relation with the business management of the association and with the active membership of the same. He would himself be responsible for a correct report of all proceedings, and be enabled to keep them without fault. The question whether or not any addition should be made to his salary for this additional work can be determined by the board of trustees. Our present secretary has served us long and well, and for his services in the past the association should, and no doubt does, feel deeply obligated to him. I am sure that he would be the first one to acquiesce in any move that would enhance the business interests or the prosperity of the association. I therefore very respectfully offer the suggestion as above stated.

SOCIETIES WHICH SHOULD BE RECOGNIZED.—In the last few months many good medical societies which have adopted the code of ethics have communicated with me, through their secretaries, asking how they could get recognition by this body. I have found, in many instances, that the State society had failed to recommend them, but for no particular reason. Anyway, they are debarred from recognition by this association. In several instances I found that said societies had a greater number in attendance at their meetings than did the State society. I trust that something will be done in regard to this matter, in order that these good societies can obtain recognition from this association.

The appointment by your nominating committee of three such distinguished gentlemen to read the several addresses before this association in general session assembled relieves me of any duty in that line. I shall therefore content myself with employing the balance of my time in asking your consideration of a few things which are a menace not only to the public health, but also to the safety of society. Having served as a health

officer for many years, my mind naturally turns into this channel, especially so when I see an opportunity to enlist the interest and co-operation of this large and influential body of physicians.

TUBERCULOSIS.—It behooves this national body of American physicians to take some action, or at least to approve the movement, to stamp out, as far as scientific effort can do so, that dread disease that kills one seventh of the world's population—tuberculosis. A few days ago, May 24th to 27th, there was held a tuberculosis congress in Berlin, international in character. The Liverpool Medical Institution, one of the most important medical societies in England, has recently appointed a committee of its members "to consider what further steps can be taken for the prevention of tuberculosis, and for the treatment of this disease in the human subject." This committee propose to consider (1) the nature of pulmonary tuberculosis, its communicability and preventability; (2) the provision of sanatoria; (3) the more effectual methods of controlling spread of infection; and (4) the desirability of adopting some form of notification. The eradication of bovine tuberculosis received a powerful stimulus throughout the empire when recently Her Majesty the Queen gave orders to have killed such of her herd of Jerseys as were shown by the tuberculin test to be infected.

At the recent meeting of the French Association for the Advancement of Science, the Section of Hygiene, at the suggestion of Professor Nicholas, passed a resolution pointing out that the convection of tuberculosis by inhalation was only one of the modes of infection, and that a larger part of the diffusion of the disease was played by contagion through the alimentary canal, as proved experimentally and clinically, urging the necessity of taking adequate measures to insure the sterilization and harmlessness of articles of food. All Europe is wide awake to the importance of this subject.

From carefully prepared statistics it is found that of the deaths from all causes between the ages of fifteen and sixty years, one third of the number are victims of tuberculosis, and that it kills four and a half times as many people as do small-pox, scarlet fever, typhoid fever, and diphtheria combined. It is estimated that at any given time in Germany alone 1,300,000 persons are affected with tuberculosis, and Osler says that 1,200,000 in America have the disease at all times. One in every fifty persons has the disease. Over 13,000 die of tuberculosis in the State of New York every year. In every American city the proportion of deaths is equally great. So important has this subject become that at a recent convention held in England to consider the question, "How to Prevent the Spread of Consumption," the Crown was represented by His Royal Highness the Prince of Wales, who presided over the meeting. Great encouragement was given the move by royalty and all others. The medical pro-

fession all over the world is deeply interested in the subject, the aid of governments is solicited, and every effort is being made to suppress this formidable disease. Since the germ which causes it is known, and its habitat, the condition under which it thrives, and it is known also that the disease is contagious, it does appear but rational to assume not only that it can be prevented by precautionary measures, but that it can be cured by proper environment and treatment. It is equally true that, even in the best of homes, the treatment usually accorded the patient is *nil* in effect and accomplishes nothing. Something more than this must be done if we expect to decrease the death-rate materially. What is that something? Detweiler believes that over twenty-four per cent. of cases of tuberculosis are curable; Meisen, twenty-seven per cent.; Braymer, twenty-one and a half per cent. And this under ordinary climatic and hygienic treatment. A much higher percentage of recoveries could be recorded if a real systematic and scientific treatment could be afforded these patients. Such a course can be instituted only in well-ordered and equipped hospitals designed especially for such inmates. In regard to the extent of the disease, I can do no better than to use the words of Professor Hirsch. He says: "It is emphatically a disease at all times, all countries, and all races. No climate, no latitude, no occupation, no combination of favoring circumstances forms an infallible safeguard against the onset of tuberculosis, however such conditions may mitigate its ravages or retard its progress. Like typhoid fever, phthisis dogs the steps of man wherever he may be found, and claims its victims among every age, class, and race." In answer to the question, What is to be done to prevent its progress? I would suggest a remedy in using the words of a resolution adopted at the International Congress of Hygiene in Brussels, in 1897: "The hospitalization of tuberculosis is urgent and will not long be withheld." In several large cities in the United States an earnest effort has already been made to carry this thought into practical utilization, especially in Chicago and New York. It can readily be seen, however, that but a comparative few out of this great number of afflicted can be accommodated in this manner. A country or State that is ever on the alert to prevent the landing of a foreign foe or a hostile army surely should ever be ready to aid in the suppression of a foe to the human race ten times more destructive to human life than the invasion of the country by an army of great size armed with the most improved rifles. Let us, then, in the name of humanity, invoke aid from the government of this very humane people, in order to help put down and thoroughly conquer this foe.

During the last session of the New York legislature a report of the senate committee appointed to investigate the advisability of establishing a State hospital for the cure of consumptives was made. Many reasons for the same were presented in the report. Among

other things, the report read: "Tuberculosis is one of the most fatal diseases that the human race has to combat at the present day; its yearly victims inflict a serious and unnecessary drain upon the resources of the State. Unnecessary because it is now demonstrated beyond question that by the adoption of proper preventive measures a large proportion of those who suffer from this disease may be saved. This is proved not only by the revelations of science but by the results which have been obtained in the practical application of the means to prevent the spread of the disease. A large proportion of the cases brought under treatment have been cured, and so many have so improved as to be restored to the producing class. It is also shown that the efforts of the boards of health in this and other States, as well as in other countries, have so far succeeded in reducing the percentage of deaths from tuberculosis by the measures adopted that there is good ground for assuming that with wise laws properly enforced this disease may be almost wholly obliterated." Is it too much, then, to suggest that this association, representing the most advanced thought of the medical profession of America, take action in this important matter? I would most respectfully urge you to appoint a committee to prepare a careful report on this subject and present it to the next congress sitting, beseeching that this government erect, prepare, or donate hospitals or reservations in and at which the poor or others shall receive treatment for the cure of consumption. Also that it be impressed upon State boards of health in the various States the advisability of the respective States erecting similar institutions. The blind, the deaf, the insane, the feeble-minded, and other classes are so provided for; why not these? They are not able to care for themselves, and they are a menace to the public health. It must be confessed that, in so far as the prevention of the disease is concerned, that must come from the education of the people to the facts. The best way to accomplish this I leave to you.

THE ANTIVACCINATIONISTS.—It may appear superfluous to ask that you consider in the proper way a rebuke to a certain class that is doing much to endanger the lives of our citizens, and whose meddling ways are giving the health boards of the various States much annoyance. I allude to the antivaccinationists, encouraged as they are by an Antivaccination Society. It seems strange and beyond belief that citizens of respectability and supposed intelligence should band themselves together to prevent a means of saving human life, but "'tis true, and pity 'tis, 'tis true." If these misguided people would only inform themselves of facts, patent to every reader of history, they might at least stop long enough in their mad career to think.

The true condition is so well described by Dr. Seys in a recent paper that I beg to quote from him: "Well has small-pox been termed 'the most terrible of all the ministers of death.' It dates back to the early history

of our race, but from whence it came no man can say. Then all expected to have it, and but few escaped. No respecter of persons, it was found in the palace and in the hovel, in the fair green fields and in the foul dungeon. All ages yielded to its noisome touch, and no season of the year was free from its deadly breath. One third of all children born to the daughters of men died before they were a year old because of this pestilence, and one half before the age of five. In epidemic years it is estimated to have caused fifty per cent. of all deaths in Europe, and in non-epidemic years not less than ten per cent. Two thirds of the pauper blind in Europe of that day looked no more on the faces of their loved ones or the blue sky, nor saw the light of day, because of its blighting visitation. In Mexico it is said in a few years to have caused the death of three million and a half of people. Iceland and Greenland were almost depopulated by it, and it has well-nigh rendered extinct some of our Indian tribes. It was the all-important factor in keeping down the population of Europe. Nor would the task be a difficult one to-day, should we desire to do so, to bring back the horrors of but a few years ago."

We may rest in peace and disregard the efforts of these half-mad people, but we must not close our eyes to the fact that, by their loud cry, aided by political influence given often for self-aggrandizement, they are endangering the lives in every community. So far has this thing gone that the vaccination law in England has but recently been amended, so that only those who may desire shall be vaccinated. This is a menace to the public health and smacks of the Dark Ages. I again respectfully ask that you give to the medical profession in America an indorsement of their views in a resolution sustaining *compulsory* vaccination. The safety of the people from this most direful malady demands it.

A CRUSADE AGAINST SYPHILIS.—An international medical conference will be held at Brussels, Belgium, in the month of September next, known as The International Conference for the Prevention of Syphilis. A statement of this fact has been sent the honorable secretary of state of the United States, through the Belgian minister at Washington, with a request that he appoint a delegation to attend this important conference. The honorable secretary, in turn, requested me, as your presiding officer, to name said delegation. This I have already done, as the call was for immediate action. In the preamble which accompanies this notice the following language is used: "The increasing propagation of syphilis and venereal diseases has become a serious danger to society, and it is important while there is still time to take efficient measures to stop the progress of this scourge. The spread of the evil is an uncontrollable fact; on this point all physicians who are in a position to know or observe its progress are agreed. The number of victims increases daily, and a serious

consideration is that this malady is penetrating into strata of society where it was formerly rarely seen. Scarcely any attempt hitherto has been made to check this social evil, or, rather, while some attempts have been made, without concerted action, without preconceived plans, and without an international understanding to success."

What can be said of Belgium in this regard can be said of the United States. Perhaps the ratio of cases is not so large, but this matters little. It is estimated that there are in this country between six and seven million people who are afflicted in one way or another with syphilis. A distinguished French authority says that one man in every four has the disease in France. When we consider that by this the very foundation of society is shaken, our families are imperiled, the constitutions of our youths undermined, our women wrecked, it is high time, as this official says, that we turn our attention to the subject. The warning should be in words that the most illiterate man or woman could understand, and it should emanate from sources and places that would reach the greatest number. Our false modesty in the past has been too pronounced, and has prevented us from giving to the common people valuable information; so we are in a measure, as a profession, much to blame for the great spread of this blighting curse.

The time has arrived when we as physicians, singly or when in convention assembled, should throw aside all restraint when dealing with this vital question. Fathers, mothers, sisters, brothers, and all others should be informed, and this information should be in the plainest language. The minister and the priest should aid the doctor in this praiseworthy undertaking. The doctrine should be inculcated into the young of both sexes that freedom from this awful condition should exist before the marriage relation is thought of. Upon this declaration rests the hope of the State, as well as of families, for neither good soldiers, good citizens, nor good husbands with tainted blood can be had. Please permit me to suggest that a committee be appointed from this body, to report at the next annual meeting, on the subject: What is the Best Means of Preventing the Spread of Syphilis?

A PLEA FOR HARMONY.—In conclusion, let me beg of you that this meeting be one of perfect harmony and peace. Let nothing of an acrimonious nature be indulged in, but rather let your deliberations be characterized by patience, love for each other, and a desire to ennoble the profession to which you belong. For are we not brothers indeed, fellow-workers for a common cause—the obliteration of the common enemy, disease? May your future life, each and all of you, be one of peace and perfect happiness; and may God grant to all a long life filled with good deeds. If fate should decree that any one of you should pass away before we meet again, may you find eternal rest in "God's next country."

SANITARY LESSONS OF THE WAR.*

BY GEORGE M. STERNBERG, M.D., LL.D.,
SURGEON-GENERAL, U. S. ARMY.

As compared with the civil war and with other great wars during the present century, the mortality from wounds and disease among our troops during the war with Spain has been low. Our wounded have, to a large extent, had the advantage of prompt treatment with antiseptic dressings, and a very considerable proportion of those who were not killed outright have recovered without any mutilating operation or septic complication. The mortality from disease has also been comparatively low; but, unfortunately, during the first months of the war, that scourge of new levies of troops, typhoid fever, prevailed in many of our camps and claimed numerous victims. It is well known to sanitarians and military surgeons that, as a general rule, more soldiers succumb to disease than are killed by the bullets of the enemy, and our recent war has not been an exception in this regard. The total number of deaths reported in our enlarged army, including regulars and volunteers, from May 1, 1898, to April 30, 1899, is 6,406. Of these, 5,438 died of disease and 968 were killed in battle or died of wounds, injuries, or accident. During the civil war the number of deaths from disease was 186,216.† The number who were killed in battle or died of wounds was 93,969, or about one half of the deaths from disease. The total deaths from disease in the Union armies from the commencement of the war to the 31st of December, 1862, was 34,326, and in the Confederate armies during the same period, 31,238.

The following table gives the monthly death-rates from disease in our armies from May 1, 1898, to April 30, 1899, and, for comparison, the rates for the same period during the first twelve months of the civil war:

Comparison of Monthly Death-Rates (per 1,000) from Disease.

MONTHS.	1861-'62.		Ratio per 1,000 of M. S.		1898-'99.		Mean strength.

* Abstract of a paper read at the meeting of the American Medical Association, at Columbus, Ohio, June 8, 1899.

† In addition to this, 24,184 deaths are recorded as from unknown causes, and probably most of these deaths were from disease.

In comparing the death-rates from disease during the year of the Spanish-American War (May 1, 1898, to April 30, 1899) and the first year of the civil war (May 1, 1861, to April 30, 1862) note should be taken in the first place that the mean strength in May, 1861, was only 16,161 as compared with 163,726 men in service in May, 1898. The mustering in of volunteer troops progressed more slowly in 1861 than during the recent war, so that it was not until September and October, 1861, that the mean strength assumed proportions equal to that of the months of the Spanish war. Although the number present in the camps of 1861-'62, after October, 1861, was largely in excess of those aggregated during the past year, the average annual strength during both wars did not differ greatly. Nevertheless, the deaths from disease in 1861-'62 numbered 10,522, while in 1898-'99 they amounted only to 5,438. The death-rate to the thousand of strength mounted gradually month by month in 1861-'62, and indeed it did not reach its acme until February, 1863, when the rate of 6.39 was reached. In 1898, on the other hand, the acme, 5.89, was reached suddenly in September, but, owing to the sanitary measures adopted, the fall during October and November was as rapid as had been the rise.

The same gradual rise is seen in the mortality statistics of typhoid fever during the civil war. The highest death-rate, 2.81, was not reached until May, 1862, the thirteenth month of the aggregation of the troops, when 1,092 men died of this disease, and the fall of the rates was as gradual as the rise. On the other hand, the rise in 1898 was sudden, the maximum rate, 3.57, being reached in September, when 933 men died of this disease; but the fall during the months of October and November was as notable as the rise. This sudden suppression of the disease can not be attributed to an exhaustion of the susceptibility of the troops to attack from this fever, as they only suffered at the rate of 12.37 to the thousand of strength during the twelve months, whereas the troops of the civil war suffered at the rate of 19.71 to the thousand. It can be attributed only to the active preventive measures that were instituted, and especially to moving the troops to fresh camp sites and to the greater care exercised in the disposal of excreta.

The following chart shows by the graphic method the same comparison as is given in the above table. The notable rise in the general death-rate from disease and in that from typhoid fever alone, which occurred in August and September, was undoubtedly due to the insanitary conditions resulting from the hasty assembling of large bodies of undisciplined troops in our camps of instruction.

The average annual mortality from typhoid fever in our regular army since the civil war has been: for the first decade (1868-'77), 95 per 100,000 of mean strength (.95 per 1,000); for the second decade (1878-'87), 108

per 100,000; for the third decade (1888-'97), 55 per 100,000. This latter rate compares favorably with that of many of our principal cities. For example, it is exceeded by the typhoid death-rate in the city of Wash-

ington in 1887 to 55 per 100,000 in the decade ending in 1897. Hygiene is made one of the principal subjects of examination for candidates desiring appointment in the medical corps of the army, and at subsequent examinations

for promotion to the grades of captain and major is given a most prominent place. It is also the most prominent subject in the course of instruction at the army medical school, where the student-officers spend five hours daily for a period of five months in practical laboratory work relating for the most part to the cause and prevention of infectious diseases. It should be remembered, however, that the army medical school was not established until the year 1893, and consequently but a small proportion of the medical officers of the army have had the advantage of this course of instruction.

But the comparatively small number of medical officers of the regular army available for duty in the large camps occupied by our volunteer troops at the outset of the war proved to be entirely inadequate to control the sanitary situation in these camps, and as a result of the conditions existing the mortality from typhoid fever in our armies during the year ending April 30, 1899, has been more than twenty-two times as

ington, which is 78.1 per 100,000 (average of ten years, 1888-'97); by that of the city of Chicago, which is 61.1 per 100,000; by that of Pittsburgh, which is 88 per 100,000. These figures, however, do not show the entire mortality in the cities mentioned as a result of typhoid fever, for without doubt many of the deaths ascribed to "malarial fevers" were in fact due to typhoid infection.

It will be seen that sanitary conditions at our military posts in time of peace, as judged by the typhoid death-rate, compare favorably with those in our large cities in various parts of the country. As a matter of fact, great attention has been given to post sanitation for many years past, and through the persistent efforts of officers of the medical department great improvements have been made, especially during the past ten years. The result is shown in a reduction of the typhoid mortality from 108 per 100,000 in the ten years ending

great as the annual mortality in our regular army during the decade immediately preceding the war period. As compared with the first year of the civil war, however, there is a decided improvement, the typhoid mortality for the first year of the civil war having been 1,971 per 100,000 of mean strength, and for the Spanish-American war 1,237 per 100,000. Moreover, as shown by the chart, the vigorous sanitary measures enforced enabled our troops to quickly free themselves from the ravages of this infectious disease, and, while the line of typhoid mortality continued to ascend during the first year of the civil war and subsequently, it rapidly fell after the middle of September last, and for the last six months of the period under consideration has been remarkably low. Indeed, in the history of large armies the record has never heretofore been equaled.

[General Sternberg then quoted from his own prize

essay on *Disinfection and Personal Prophylaxis in Infectious Diseases* and from the *Manual for the Medical Department* as to the proper measures to be taken for the disinfection of excreta, soiled bed linen, underclothing, etc.; and further reproduced Circular No. 1, issued from the surgeon-general's office at Washington on April 25th, and summarized in the *New York Medical Journal* for August 20, 1898, giving the most explicit sanitary instructions to medical officers as to sinks, kitchen refuse, fluids to drink, isolation of infectious cases, sanitary policing, avoidance of marches during the heat of the day, use of fruit and quinine, and proper underclothing. Circular No. 5, dated August 8, 1898, calling renewed attention to Circular No. 1 and enforcing its provisions, and Circular No. 7, dated September 5, 1898, calling attention to the paragraphs relating to the disinfection of excreta from the *Manual for the Medical Department*, were also quoted.]

The reasons are apparent, and even in the light of our recent experience I am not sure that under similar conditions we could avoid similar results. Sanitarians generally are familiar with the difficulties attending their efforts to restrict the ravages of infectious diseases in towns and cities. They have to contend with the ignorance and reckless indifference of a large proportion of the population, with the ignorance and mistaken parsimony of legislative bodies, and to some extent with the negligence or perfunctory performance of duties assigned to them by agents of the health department, often appointed as a reward for political services rather than on account of their special fitness for the work. Perhaps it was too much to expect that typhoid fever should be excluded from our camps, unprovided with sewers and occupied by new levies of troops, having for the most part inexperienced officers both of the line and in the staff departments. The medical officers of regiments were appointed by the governors of States, and, as a rule, were competent professionally, but they were called upon to assume new responsibilities for which they had no special training. Unfortunately, hygiene and practical sanitation are subjects which receive little attention in our medical schools or from physicians and surgeons engaged in the practice of medicine. But even in those cases in which the regimental surgeon was fully aware of the importance of camp sanitation and urgent in his sanitary recommendations, he was unable to control the sanitary situation unless the regimental and company officers enforced the necessary measures for protecting the health of the command. And just here is the fundamental difficulty when we are dealing with new levies of troops. The officers and enlisted men of our volunteer regiments were, as a rule, intelligent, patriotic, and brave, but they were not disciplined. Each man was in the habit of judging for himself and of acting in accordance with his individual judgment. Discipline consists essentially in an unquestioning obedience to orders from those

having proper authority to give them. Trained officers can not at once establish discipline among untrained troops, and when both officers and enlisted men are without military experience, it is evident that, with the best material, time will be required for the establishment of discipline. And in the absence of discipline it is impracticable to enforce proper sanitary regulations in camp. The surgeon-general may formulate sanitary regulations, and the general commanding an army corps or a division may issue the necessary orders, but in the absence of discipline these orders will not be enforced. A reckless recruit *will* drink the water which has been condemned as unsafe, and at night *will* defile the ground in the vicinity of his tent rather than visit the company sink, which, possibly, is in a disgusting and unsanitary condition because of a failure to carry out the orders to cover the surface of excreta "with fresh earth, or quicklime, or ashes, three times a day."

And now, in order that the "sanitary lessons of the war" may not be lost sight of, and may be made available hereafter if we should again have occasion to assemble a large army on short notice, I consider it my duty to speak plainly with reference to one of the principal causes of the epidemic prevalence of typhoid fever in our camps. As a rule, this disease was called by some other name by the medical officers on duty with regiments who first saw the cases. Usually it was assumed to be malarial fever, and was treated as such until the patient became so sick that it was found necessary to send him to the division field hospital or to a general hospital. This general statement is based upon the carefully made investigations of a board of medical officers appointed upon my recommendation.

In a paper read by Major Victor C. Vaughan at the meeting of the Association of American Physicians, held in Washington city early in May, which paper may be regarded as a preliminary report of the board, the following statements are made:

"We had not finished our first day's work at Camp Alger before we saw that one factor in the problem must be thoroughly dealt with before we could hope to reach a satisfactory solution. Fortunately, we promptly took steps to acquaint ourselves with this factor. It can not be denied that scientific medicine would have gained much had this factor been provided for at an earlier date. I refer to the question of the scientific diagnosis of typhoid fever. In the division hospital at Camp Alger we found most of the febrile cases diagnosed as malarial. We believed that they were typhoid fever, but the surgeon in charge had diagnosed them malarial. We requested that competent men, properly equipped for making blood examinations for the malarial plasmodium and the Widal test, should be sent to each of the larger camps. The surgeon-general acted promptly on this suggestion.

"When we began to study the regimental sick reports we found that, in order to obtain satisfactory in-

formation, we must endeavor to ascertain how many cases of typhoid fever there were in each regiment, and it soon became evident that the regimental sick reports did not give this information. Of two regiments in the same brigade, one had more than two hundred cases of typhoid fever, as shown by the regimental reports, while the other regiment on like evidence had only two cases; but the records of the second regiment show more than two hundred cases of protracted malaria, and these furnished a mortality as high as that of the typhoid fever in the first regiment. For the reasons already given, we have included all the protracted malarias among our list of the typhoids. It may be asked how long we have considered it necessary for a so-called malaria to run in order to make it a probable typhoid. In answer to this I will state that we have regarded all so-called malarias of ten days or more in duration as possible cases of typhoid fever. We think that the great rarity of true malaria, and the readiness with which these rare cases have yielded to quinine, and the fact that quinine was so generally administered, justifies us in this conclusion. Practically, however, the number of doubtful cases is exceedingly small.

"Typhoid fever was not only diagnosed as malaria, but it was covered up by many other names. In one regiment the death-rate from indigestion amounted to fifteen per cent. of the completed cases. In another regiment at Chickamauga dengue is a frequent diagnosis of many cases which undoubtedly were typhoid fever. . . ."

This failure to recognize typhoid fever during its earlier stages is an error of diagnosis which was made on a very extensive scale during the civil war, has been made on an equally extensive scale by surgeons of the British army on duty with troops in India, and is still being made by a majority of the practitioners of medicine in certain parts of our own country.

[The surgeon-general then made extensive quotations from his own work on *Malaria and Malarial Diseases*; from Dr. George B. Wood's *Practice of Medicine* (ninth edition); Dr. James C. Wilson's *Treatise on the Continued Fevers*; Dr. W. W. Johnston's paper (*American Journal of the Medical Sciences*, October, 1882) On the Mild Forms of Continued Fever which Prevail in Washington; Sir Joseph Fayrer's recent work on *Fever in India*; and from Professor Borelli's articles (*Medical Times and Gazette*, London, July 8, 1876) on Naples Fever, all tending to substantiate the thesis that the mistaken diagnosis of typhoid fever as malarial fevers of various kinds prevailed very widely, though not more, perhaps, in this country than in continental Europe and British India. The great difficulty of forming an early correct diagnosis from clinical symptoms was emphasized; inasmuch as while remittent fevers frequently assumed in their later stages a continued form, and malarial fevers of a remittent or continued type often gave rise to a "typhoid condition," typhoid

fever, on the other hand, frequently showed a decided remittent character during the first week quite independently of any malarial complication, and still more so when occurring in a malarious subject. The error in diagnosis once made might be persisted in in the later stages, either under the continued influence of the preconceived and dominant idea, or from the reluctance to confess to an error.]

Finally, the principal lessons to be derived from our recent experience may be stated as follows:

A trained medical corps, hardly adequate for an army of twenty-five thousand men, can not control the sanitary situation when this army is quickly expanded to two hundred and fifty thousand. Physicians and surgeons from civil life, however well qualified professionally, as a rule are not prepared to assume the responsibilities of medical officers charged with administrative duties and the sanitary supervision of camps. The proper performance of such duties can not be expected from a physician without military training or experience, no matter how distinguished a position he may have held in civil life.

Courage and patriotism on the part of line officers and enlisted men can not take the place of knowledge and experience. New levies of troops are, as a rule, ignorant of the first principles of camp sanitation, and reckless as to the consequences of their neglect of prescribed sanitary regulations. Therefore training and discipline are essential factors in the preservation of the health of soldiers in garrison or in the field.

The value of the aphorism "In time of peace prepare for war" has received additional support. This preparation should include a corps of trained medical officers larger than is absolutely necessary for the army on a peace basis, and systematic instruction in military medicine and hygiene for the medical officers of the national guard as well as for those of the regular army; also instruction of line officers in the elements of hygiene, and especially in camp sanitation. It should also include the establishment of camping grounds in various parts of the country, having an ample supply of pure water, a proper system of sewers, etc. If our volunteers could have been assembled in such camps during the late war a saving in lives and money would have resulted which would without doubt have demonstrated the economy of such preparation for war in time of peace.

THE VOICE IN DIAGNOSIS.*

By ALEXANDER J. C. SKENE, M.D.

I. INTRODUCTION.—The easiest and most interesting method of studying the voice in all its relations to health and disease is to begin at the beginning of the development of language and follow its evolution from the first

* Read before the Brooklyn Medical Society, March 17, 1899.

audible functions of a primitive larynx up to the mature speech of the highest types of the human race.

The demands of professional life do not permit of our doing more than glancing at some of the leading principles of the subject. It must suffice for our present purpose to recall the fact that lower beings express their thoughts and feelings by a very limited number of sounds, that are multiplied as creatures ascend in the scale of brain development. The primitive races in the human family having small brains that are not extensively cultivated, their mental powers are limited. They have few ideas, thoughts, and emotions, and hence have few words in their language, and they speak in a monotonous way. Having no extensive range of thought or marked shades of meaning, they express themselves without any great range of modulation.

As the brain grows in size, power, and activity, the voice develops to meet the requirements of the mind, until we have in our day that infinite variety of voices, beginning with the uncouth babbling of the savage, up to the orations of Demosthenes and Webster; from the wild, weird chant of the dusky maid in darkest Africa, to the singing of Patti and Melba.

The development of the voice in infancy and childhood follows the law of evolution observed in the lower animals, and as that comes under our observation we can learn much that is needful in our everyday routine. Indeed, before we are aware of it we acquire a wonderful comprehension of this apparently complex subject. Fortunately, we learn all the characteristics of human voices as we personally learn to speak the language of our parents, through the sense of hearing; and when we begin to apply our knowledge, unconsciously acquired in childhood, to our scientific work in the profession of medicine, we have only to review and arrange the facts according to the process of natural evolution.

II. THE VOICE AS AN AID IN DIAGNOSIS.—The voice and its modifications indicate the conditions of body and mind more clearly than any other factor in the long list of physical signs and symptoms presented to the physician for his guidance in the great science and art of diagnosis, and, strange to say, very little attention is given to the subject by writers and teachers of medicine and surgery, so far as I know. I am bound to say in justice to others that my opinion on this part of my subject is based upon the fact that a rather extensive reading of the literature of diseases of women discloses a notable silence regarding the voice. If, however, I am unjust to others whose labors may have escaped my notice, I trust you will correct my sins of omission.

As this communication is intended to be suggestive, rather than elaborate and comprehensive, it may, I trust, not savor of pedagogic autocracy to state, by way of recalling familiar facts, that there are three factors of interest in the production of the voice: First, the larynx, or vocal organ; second, the motor power, or respiratory

system; and third, the directing, controlling agency, innervation. Necessarily there must be back of all these a psychological mainspring, the nature and relationship of which may be determined according to the way of thinking of my hearers individually and collectively. Recalling these facts and the infinite variety of bodies and minds concerned in the production of voices, leads up to the different types of natural voices with which one must become familiar before undertaking the study of changes produced by disease. The subject is rather complex, yet none the less interesting, because of the vast variety of modulations and intonations employed in speech, to fully express all the ideas, thoughts, and emotions of the mind. If human beings spoke in monotone one could soon learn to distinguish the different types of normal voices, and as easily learn the changes and modifications of character, intensity, pitch, volume, and sustaining power. The voice used in quiet narrative or description, in logical argumentation, and in expressing the stronger emotions, such as fear, anger, joy, and sorrow, must first become familiar to the diagnostician before he can avail himself of these characteristics as evidence of disease. When one recognizes the fact that there are as many kinds of voices as there are of faces in this world, he may despair of ever being able to familiarize himself with the natural voices as heard in everyday life; but a little careful observation and thoughtful study soon reveals the fact that there are a few types which are readily recognized, and that all others are simply modifications of the leading distinctive ones. First, there is the immature child voice, which is untrue; that is, it is characterized by being a fraction of a tone above or below the normal key. This is the natural voice of childhood, and when once understood becomes familiar and easily remembered. Some adults retain the child voice, the significance of which will be referred to later on. Then there is the soft voice of the timid, bashful person, a variety of which is found in the cautious, cunning one, who often drops into a whisper in conversation, although alone with his auditor. The quiet, clear, musical voice of the educated person who speaks correctly is the highest type, and is in marked contrast with the loud, strong voice of the self-confident, aggressive one, whose head is usually small and round, while the stomach is large and powerful in proportion to its size. The low-pitched voice of the uncultivated who talk in monotone; the high-pitched voice of those of the nervous temperament who talk rapidly and in staccato. The voice that may be of any pitch, but is used in a hesitating, drawling sort of way, if musical and agreeable, belongs to the thoughtful; but if in the minor key and acutely accented, betokens a vinegarish element, either of peevishness, dissatisfaction, or sarcasm. These are a few of the types which require to be familiarized by observation, not only as a preparation to the study of voice changes as indicative of disease or derangement in given cases, but also as a valu-

able indication to assist the practitioner in determining the mental, and to some extent the physical, make-up or personality of each of the many who come under his care. All this may appear to be a most complex and obscure subject, difficult to master and not easy to put in practice; but it is no more so than to take into account constitutional peculiarities and idiosyncrasies. To one possessing an acute sense of hearing the subject is so interesting that knowledge is acquired regarding it with a facility that gives pleasure instead of by painful, laborious work; indeed, to one with good hearing much of the required knowledge comes unconsciously through contact with those about him in daily life and before taking up the study of medicine.

In order to follow the subject in something like systematic or natural evolutionary order, the voice modifications which indicate the condition of the mind at the time of examination should be considered. This naturally follows after acquiring a knowledge of the various types of voices and becoming acquainted with the normal voice in those who come under the practitioner's attention. Bearing in mind always that the function of the larynx is dominated by the brain and nervous system, the voice itself, to a great extent, expresses the state or attitude of the mind more truly than the words spoken. *The tongue may lie, but the larynx tells the truth.* The words spoken may purposely conceal the thoughts, and thereby deceive by conveying wrong impressions; while the character of the voice betrays the true feeling at the time of the articulate speech, whatever it may be. The modulations, intonations, pitch, degree of resonance, and other modifications of the voice change the meaning of words; so that one sentence spoken in different ways conveys to the hearers very different ideas. It is because of this that a remark like the following is so often heard: "It was not what he said, but the way in which he said it, that offended me—pleased me—or made me suspect him." Another good illustration of the misleading character of words used and the truthfulness of the voice that speaks them may be observed in women who, desiring to conceal their sorrows, talk cheerfully, but have tears in their voices. (The latter phrase is borrowed from the language of the artist.) This shows that the voice has a natural history of its own, which plays an important part in making up the natural as well as the clinical history of every human being, and, while it can be made to express or conceal certain marked states of mind and body, it takes an equally important part in the development of the clinical history of nearly all known diseases. The voice as an evidence or index of certain states of the mind which are normal under certain circumstances is illustrated in the following: In a person who is in ill-humor temporarily the voice is confined usually to the middle register and he speaks in rather slow time. This is popularly known as growling. The voice in strong anger, wrath, or rage is harsh in character, high in pitch, somewhere

in the upper register, in faster time, and punctuated with deep, rapid respirations. The consonants are emphasized, and the voice, when lowered in resonance, gives the hissing voice of the stage villain. The harshness of the voice is perhaps due to the extreme tension of the muscles of the neck and larynx. Contentment or pleasure is indicated by a rather low-toned voice, musical in character, and of middle register and pitch. In some cases the voice has an element approaching laughter. In joy or glee, the voice is higher pitched, more intense in character, and of good volume, generally interrupted. This is expressed by the laymen as shouting for joy, or screaming with delight. Dread, apprehension, and doubt are shown by the voice being slightly tremulous, imperfectly sustained, low-pitched, uncertain in resonance, and interrupted. The voice of fear or fright is high-pitched, staccato, or whispering, if the fear is intense. In women it is often thin in character, wanting in resonance, and screaming or screeching in tone and tempo. The voice of sorrow is low, soft, tremulous in character, not well sustained, but inclined to be continuous, or approaching to the singing voice, and in the minor key. The chief interest for the physician is to know how to distinguish the voice of sorrow from an imitation. Many patients try to talk in a sorrowful way, but they simply grumble in a minor key, and the voice of the imitator is generally more harsh and higher pitched than the genuine voice of the truly sorrowful. They fail to produce the quiver or tremolo. No one but a consummate artist can counterfeit the voice of sorrow, and then only in singing; rarely, if ever, is the imitation well made in speaking. These are only a few hints regarding certain ways in which the voice changes express the physiological mental attitudes.

With this meagre introductory basis I may take up the subject in its relations to diseases in infancy and childhood. Infant patients being unable to express their aches, pains, and suffering in words, the physician has to depend upon other signs in making a diagnosis; consequently the voice should be carefully observed. Of necessity this needed attention has been given in pædiatrics, I presume, more fully than in dealing with adults. Ordinarily students are taught to recognize the piercing screech as diagnostic of cerebral meningitis, which, once heard and its meaning understood, is not forgotten. This voice sound, or a similar one, is occasionally uttered at the beginning of a convulsion. It is therefore an unnatural voice, being only heard in cerebral affections, and is in a marked degree diagnostic. Crying is the only way in which an infant can express its wants, and it may be said that there is a natural cry in infancy which is not expressive of any kind of suffering and has nothing of the nature of weeping in it. I have heard that infants never cry unless they are sick or suffering. *That may be true of children, but not of infants.* Infants cry vigorously when they want food, though not painfully hungry. They often

awake from a sound sleep and, if not nursed, cry until they are fed. On the other hand, infants who seldom or never cry are often found to have serious organic disease—hydrocephalus cerebri, for example. The cry which indicates some slight irritation of the mucous membrane of the alimentary canal, such as intestinal indigestion, or disturbance of the skin from heat, cold, or annoying clothing, is so near to the natural cry that it is not easily distinguished or described. From the ordinary cry, which may be called normal, it differs in several respects, according to the degree of discomfort suffered by the patient, and its temperament or personality. Some of the characteristics are that the cry is louder and more intense, and the screams follow each other in rapid succession; or the sound is begun in a high pitch and falls abruptly; or the sound ends in a higher pitch than that in which it began. In more pronounced indigestion or skin irritation the cry is more intense and prolonged, or continuous, with only a pause of a moment or two now and then. There is occasionally an abrupt rise in pitch, giving that ill-natured element which is irritating to the hearer and usually is supposed to be an expression of temper. Such infants are called by spinsters and bachelors “spunky,” and are said to cry wickedly. Infants who are weak from imperfect organization or exhausting disease, when suffering from temporary irritation, change their voices from the low and intense to a plaintive wail. The thin quality of the voice, high pitch, and increased flatness in tone give the characteristics of the weak and suffering infant. All these attributes increase as the patient becomes weaker, and disappear gradually if strength and relief are obtained. Spasmodic, intermittent pain, which occurs in the acute indigestion of infants, produces a cry which is loud, intense, and violent, with intervals of complete repose. This cry can usually be distinguished from the crying that is less intense and aggressive, which occurs in the muscular and joint pains of rachitis. In peritonitis the cry is suppressed: that is to say, the attack is well made, but ends abruptly, and is sharp or shrill in many cases.

The voice changes in diseases of the respiratory organs in infants are necessarily many and varied. I shall refer in brief to only a few of those which are most valuable in the investigation of the more common diseases. The loss of voice and the various degrees of its modification and impairment in laryngitis are so well understood that I shall pass over this part of the subject.

In rhinitis, with closure of the anterior nares, the resonance of the crying voice is diminished, and is continued in a stentorian, imperative way, at least in the beginning of it. There is a certain voice sound characteristic of bronchial and pulmonary diseases, such as grunting respiration, as it has been called, which is a soft, low, short sound, made at the beginning of each expiration, which occurs in certain stages of all acute dis-

eases of the lungs and bronchi, but is most perfectly developed in inflammation of the smaller bronchi, capillary bronchitis, and lobular pneumonia. At the close of the inspiration there is a short, abrupt pause, and at the beginning of the expiration the sound is emitted. Musicians would say that this was a chest note, showing a diminution of the thoracic or chest resonance.

In lobular pneumonia and pleurisy with effusion, there is a similar sound produced at the beginning of each expiration, but it is a little less prolonged and much less resonant, owing to the solidification of lung tissue from the products of inflammation or condensation of the lung from the pressure of fluid in cases of pleurisy. Not infrequently this sound is absent altogether, especially in the advanced stages of the disease. Sometimes the sound is more of the nature of a low, soft, superficial moan, and is often continued in sleep. Occasionally it subsides altogether for a time, to return after an attack of coughing or a change of position.

From the age of five years, or thereabouts, up to puberty, the voice in disease is much the same as in adults, excepting that the characteristics of the undeveloped, immature voice continue and to some extent modify the voice signs of morbid states. A consciousness of being incompetent to discuss the infantile part of the subject has rendered me timid, and hence brief and unsatisfactory. In fact, I had only a few years of practice among children; so that which is here presented comes more from memory than from present knowledge.

The voice modifications caused by disease in adults may be classed according to the agents concerned in the production of the voice. There are, as already stated, the larynx, tone producer; chest, throat, mouth, and nasal cavities, which produce the overtones, or supplementary tones of the voice; the respiratory organs, which supply the motor power; and the primary coordinating brain and nervous system.

Derangements of the voice due to lesions of the larynx itself, and affections or derangements of the nervous system and circulation which affect the functions of the larynx, are usually manifested by various forms and degrees of hoarseness and loss of voice, partial or complete.

Hoarseness indicates either acute or chronic inflammation of the larynx in various degrees or stages. There are certain structural changes of the vocal cords produced by inflammation, tuberculosis, or syphilis, indicated by a hoarse, whispering voice, which is permanent, and suggests that the primary morbid process has subsided, but left the vocal cords in such a condition that they can no longer perform their function.

The laryngologists may be able to distinguish the pathology from the various kinds of hoarseness, but of this I have not learned anything from them.

The loss of voice—aphonia—indicative of deranged innervation is characterized usually by the absence of

all effort at speaking. The best illustration of this is found in hysteria, familiar to all practitioners. In many cases it is feigned, like most of the other symptoms of hysteria. Hysterical or nervous aphonia is distinguished from loss of voice due to laryngeal disease by the fact that in the former there is no effort made to produce sounds, while in the latter strong efforts are made to use the voice, which results in whispering in a hoarse or soft way.

These voice signs of disease are well defined in works on practice of medicine, and are mentioned here as suggestive of how valuable they are and have been in turning attention to the subject as related to all branches of medicine and surgery.

III. MORBID STATES OF THE VOICE INDICATING LESIONS OF CIRCULATION.—The voice is husky, tremulous, and not well sustained in mitral insufficiency with compensating cardiac hypertrophy. The quivering or shaky voice in this form of heart disease, which I have called tremulous, is very different from the tremolo of the singing voice, or the trembling voice of strong emotion, which is musical and expressive of certain normal conditions. The one is in regular, even waves of vibration, the other (caused by the morbid heart action) is irregular in degree and rhythm. At times the shakiness is marked, and again absent.

The husky quality of the voice when present in heart disease indicates hyperemia of the vocal cords, and is the same as the husky voice often found in Bright's disease, which is due to œdema, and very like the rough, harsh voice of the habitual drinker.

The voice becomes high-pitched, soft in quality, and ill-sustained in aortic insufficiency, and is a great aid in distinguishing the two forms of heart diseases.

The various blood states have a marked influence upon the voice, changing it so that it reveals the cause of its variety.

Hyperemia, as already stated, lowers the tone of the voice and modifies the tone quality, according to the degree of congestion.

Anæmia raises the pitch of the voice, renders it thinner in quality, and if forced, it is quite intense, but is not well sustained and is apt to break from time to time. It is not easy or always possible to tell the modifications of the voice which occur in anæmic conditions from those that are present in certain conditions of the nervous system—fatigue, debility, and exhaustion, for example. The impairment of the voice in anæmia is rather uniform, while in nervous exhaustion it varies in degree.

Dehydrated blood—that opposite state to the hyperæmia which is more familiar—produces the most marked changes in the voice. This is best illustrated in Asiatic cholera. In the second stage of this affection the voice becomes very high-pitched, thin in quality, then a whisper, and finally is lost completely. Similar changes occur in cholera morbus and other affections

in which the quality and quantity of the blood supply are changed.

The weak, soft voice in acute anæmia from hæmorrhage is distinguished from that of dehydration by its being low-pitched, owing to relaxation of the vocal cords. It is always weak and at times whispered.

This loss of strength, volume, or resonance of the voice—which comes on, not always suddenly, but gradually, and yet in a short time—is a most valuable sign of concealed hæmorrhage, such as the secondary hæmorrhage which occurs after abdominal operations, and also in post-partum hæmorrhage.

In surgical cases the weakening of the voice comes on gradually, the time required to effect the changes depending upon the size of the bleeding vessels. The value and reliability of this sign of hæmorrhage in the voice depend on its being the first in the clinical history to be observable. The voice beginning to fail is the first sign or warning that the much-dreaded hæmorrhage has begun. The attention of the surgeon being attracted by the modifications of the voice, other evidence is sought for, and the suspicion aroused is confirmed and a diagnosis made while there is yet time to give relief. In case the warning voice passes unheeded or is not understood, the hæmorrhage goes on until the time to save life by arresting the bleeding is past.

When bleeding starts in the peritoneal cavity, pain usually comes on; but pain is often present from other causes, and it is not recognized as evidence of hæmorrhage, at least not until it has gone on to a very dangerous extent. I hold, then, that the voice is the first to show the effects of concealed hæmorrhage and to proclaim, not in words, but by its change of attributes and characteristics, that the much-dreaded event has occurred, dreaded the more by the surgeon, because the operator is responsible for secondary hæmorrhage; and in the majority of cases he can control the bleeding and save the patient if the diagnosis is made in time.

One whose attention has been turned to this subject may be able to make use of the change of voice in detecting concealed hæmorrhage without noting all the elements of the change. A change is noticed, and the observer is put on the right line of investigation, which, with the aid of other signs and symptoms, leads to a correct diagnosis.

Sudden and profuse hæmorrhage, such as may take place post partum, affects the voice abruptly and in much the same way as in syncope. Therefore it is not always possible to say whether the voice signs arise from hæmorrhage, fainting, or sudden shock; but the voice signs are none the less valuable because they direct attention to the state of the patient and indicate that some one of these morbid states is present, and a distinction can, as a rule, be easily made through the additional evidence present.

IV. THE VOICE AS AN INDEX OF THE CONDITION OF THE NERVOUS SYSTEM.—It is in this department of in-

vestigation that I have found the voice changes of most importance. In all morbid states of the nervous system, acute and chronic, the voice is changed, and each deviation from the normal is diagnostic of the conditions which produce the changes presented.

V. THE VOICE BEFORE AND AFTER MAJOR OPERATIONS.—One of the most important parts of the clinical history which the surgeon ought to know fully, before and after major operations, is the condition of the nervous system. The temperature, state of the circulation, and general nutrition—in short, the condition of all the vital organs of the body—can be easily and clearly determined; but the less marked deviations from health and strength of the nervous system are not easily made out. The milder forms of neurasthenia are not well manifested, and the symptoms of nervous weakness that may be present are often overlooked, or, when apparent, are often attributed to fear of the operation, want of courage, and so on. Even the voice signs of nervous weakness and nervous depression are not pronounced, and when they are present one finds it difficult to determine whether they indicate a degree of exhaustion, temporary depression, or fatigue. Still, by watching and repeated examinations, a diagnosis can be made in most cases. This is of far more importance than at first appears, but may be fully comprehended by considering two cases as nearly alike as can be imagined: One patient bears operating well and recovers promptly, while the other either dies or makes a tedious convalescence. The cause of the difference is in the nervous system. The one is strong, the other is weak. I contend that the difference between the two is manifested in the voice, the one being normal and the other morbid.

VI. THE TESTIMONY OF THE VOICE AFTER MAJOR OPERATIONS.—The voice in surgical shock is reduced to a minimum of volume and resonance, the degree of loss of voice being in keeping with that of shock. In severe cases the voice is often reduced to a whisper, and is only made audible by an effort on the part of the patient. Even the forced voice shows a marked diminution of volume and resonance, is husky and ill-sustained. Patients often decline to speak in an audible voice because it requires more of an effort than they are able to make. Failure of the voice is the first evidence of shock, I presume. At any rate, shock affects the voice as soon as it does the pulse, if not sooner. This, of course, has not been noticed, owing to the majority of subjects being anesthetized when the shock is caused. I have had an opportunity to see many cases of shock from injury, and in all of them the voice gave way first. On that account I have depended upon the voice signs in making a diagnosis more than upon any other sign or symptom, and have seldom, if ever, been mis-guided.

Equally reliable are the voice signs in showing reaction from shock. Improvement in resonance and power of the voice is the first sign of recovery. Sev-

eral times it has happened that my assistants and nurses have reported that there were no signs of improvement, and they were discouraged in consequence; but, finding an improvement in the voice, I have encouraged the vigorous continuance of the treatment, and success has followed.

VII. THE VOICE IN APATHETIC CONDITIONS OF THE NERVOUS SYSTEM.—There is a peculiar state of the nervous system into which patients sometimes fall after grave operations, which has never been fully described, so far as I know, which is characterized by indifference. It seems as if the nervous system became overwhelmed and gave up its function of displaying the danger signals. The vital forces apparently give up the task in despair. There is no alarming change of temperature or pulse; the patient makes no complaint of any mental or physical suffering, and yet the condition is a most grave one and most deceptive, leading the attendants to be hopeful and free from apprehension until death comes as a surprise to them. There are no signs or symptoms that are diagnostic. Even the face is placid; the voice, manner, and mental action are the only indications that there is something far wrong. Even the mental condition is not always apparent to the casual observer. The abnormal voice alone tells the story.

All that I have ever read or heard about this condition, following grave surgical operations, is embodied in a story told by J. Marion Sims. Not knowing where to find the story as told in Sims's graphic way, I can only give the facts from memory.

Sims was in Edinburgh and had seen Keith do ovariectomy in a very bad case. Two days after he called on Keith and anxiously asked about the patient's progress. Keith said she was doing badly, expressed grave doubts about her recovery, and added, "Come and see her." This was just what Sims wanted to do, so he went and examined the patient, looked over the record of pulse and temperature, and inquired about her nourishment. Then the two worthies retired to an adjoining room to discuss the case. Sims expressed great surprise at Keith's gloomy view of the patient's condition, adding that she was in remarkably good condition for one who had undergone such a severe ordeal. Keith replied that he "did not like her; that he was afraid that she would not do." Sims wanted to know on what grounds he based his unfavorable prognosis. "Well," said Keith, "my old nurse, who has cared for so many of my cases, does not like her condition, and I have great faith in her opinion. She is seldom mistaken." Sims asked to have the nurse called in to find out her reasons for the doubts and fears. Mrs. Dow, the nurse, in reply to the doctor's direct questions, said that "the patient was too good; she was indifferent, wanted nothing, was pleased with everything that was done for her, and those cases do badly," she said. "I like ones who are hard to please; the devils always do best." "Yes," said

Keith, "that's it—she is indifferent; her nervous system is giving out."

After reading this brief essay by Sims, I discussed the subject with Keith, and have been on the lookout for such cases and have seen several of them. They are very obscure. There are none of the well-known signs and symptoms present to warn the attendant of the danger, except the voice changes and the mental attitude of the patient. The voice is negative, so far as expressing any feeling such as pleasure, sorrow, irritation, ill temper, or anxiety is concerned. This negation or indifference manifested in the voice is nearly always mistaken for contentment, and is therefore misleading. The pitch is lower than normal and the intensity diminished. Many times the speech is inclined to be spasmodic, abrupt, more jerky than usual. There are many pauses in the sentences, the patient being apparently short of breath. The voice occasionally breaks or fails, but is never forced.

In this it differs in a very noticeable degree from the voice in acute prostration, in which it is ill sustained and often forced, and hence higher in pitch and more intense while it lasts. This condition of irritability and general hyperesthesia, which comes on after the depression that immediately follows operations, and in many cases continues for a long time, is plainly expressed in many ways and is easily detected without taking the voice into account except incidentally. But the voice signs peculiar to this condition of the nervous system should be understood in order to be able to distinguish between this and the voice of the used-up nervous system, in which the voice gives the leading evidence.

Knowing the normal voice in a given case, one can easily observe that it becomes higher in pitch, more abrupt, more intense by being forced and more irregular in its intensity, that it is not well sustained, and is either plaintive or peevish, according to the disposition of the patient and the stage or degree of the affection. After a period of repose such a voice becomes husky, but clears up after an effort on the part of the patient. This huskiness is more likely to occur if there is fever present. It may suffice to say in this connection that every gain or loss of strength, especially of the nervous system, is first indicated in the voice, in the vast majority of cases.

Having given most attention to surgical cases, I have become more familiar with the voice signs as related to the conditions of this class of patients. Now, as a matter of routine observation, I note the state of the voice first, take the temperature and pulse, and finally complete the examination.

VIII. THE SIGNIFICANCE OF VOICE EXPRESSIONS OF PAIN AFTER ABDOMINAL OPERATIONS. The irregular, subacute pain of intestinal colic, so often found in this class of cases, is indicated by the patient holding the breath for a time, and then in a rather low pitched

voice complaining in a groan, grunt, or exclamation, such as a prolonged "Oh!" "Ah!" and the like.

The intermittent sharp, short, high-pitched screech or scream is characteristic of the pain of peritonitis. Sometimes the cry is violent, and again it may be faint; but always short and abrupt and shrill; generally in a minor key.

This language of voiced expression of pain, if I may use this term, is far more reliable evidence in the clinical history than the average description of suffering given by patients.

Some years ago, while engaged in studying the relations of diseases of the sexual organs to mental disorders, I observed many peculiar voices among the insane. Something unnatural in the voice was heard among all these crazy subjects, but I never had time to determine their meaning so that I could utilize the evidence in diagnosis. I only progressed far enough to be able, or to fancy that I was able, to recognize the voice of one who was insane. This was sufficient to interest me greatly in the subject and make me look to the neurologists for further information. Up to the present time, however, the voice in the various mental affections is still in the shades of obscurity, and though the field is ample, in my opinion, and very interesting, I fear that I shall not have time to cultivate it. I must, therefore, leave this part of the subject to those who have the ability and opportunity to solve the problem.

In conclusion, I may say that to those who have never given any attention to this subject my remarks must appear rather obscure, and that, in order to make this means of diagnosis of any practical value, a great amount of time and practice must be required. I admit also that one must have the sense of hearing in a normal state, so that the varieties of quantity and characteristics of sound can be appreciated; but it is not necessary to be versed in the science of music, or to comprehend the art of tone production, modulation, coloring, phrasing, intensity, pitch, volume, and character of the voice to be able to detect the derangements of the voice that are caused by disease and expressive of the diseases that cause them.

One's hearing must be correct to master auscultation, and yet one need not be skilled in the science of acoustics, with all its multiplicity of laws, in order to master auscultation and percussion. So it is in voice interpretation or sound reading. Much practice and observation are necessary to become an expert in reading by sound the language of disease as expressed by the voice produced under deranged conditions of action. This may be made more complete by referring to the fact that one learns to recognize all the various kinds of respiration that occur in all the diseases, while the physiology of respiration may not be fully understood. Many a good practitioner can recognize with great promptitude deranged breathing and understand the cause of the character of it, yet might not know the

anatomy and physiology of the bronchial and vesicular elements of inspiration and expiration, their character, intensity, pitch, and relative duration.

So it is with the voice. One may be able while in practice to detect signs of disease in certain derangements and modifications of the voice, and yet may be unable to make an analysis of the attributes of that voice or give any technical description of it that could be recognized by another.

VAGINAL DOUCHES, ANTE-PARTUM AND POST-PARTUM.

By L. NAPOLEON BOSTON, M. D.,

BACTERIOLOGIST TO THE PHILADELPHIA HOSPITAL;
INSTRUCTOR IN OBSTETRICS, MEDICO-SURGICAL COLLEGE,
PHILADELPHIA.

IN the past, and even at present, it is extremely common to find obstetricians and general practitioners who are especially fond of giving vaginal douches, and use them as routine treatment instead of dealing with the douche as with forceps, premature labor, and abortion, having certain distinct indications for its use.

Douches may be divided into three varieties: Hot, cold, and Scotch (hot and cold alternately), any of which may contain certain chemicals which render them more or less antiseptic.

The lining membrane of the vagina is in many respects similar to that of other mucous surfaces, despite the views of Pretti, who states that it is merely an invagination and contains none of the essential properties of mucous membrane. It is therefore fair to conclude that any interference with its normal condition can do no good, and may do harm. The vagina is usually well lubricated by a rather tenacious secretion of acid reaction, probably due to the action of the bacillus of Doderlein. With few exceptions the vaginal secretions are increased during the latter months of gestation and after labor—a physiological provision against infection during delivery and the puerperium, since the ordinary pathogenic bacteria can not reach the uterus without first becoming entangled within the meshes of the vaginal secretion, which by its tenacious property prevents their reaching the uterus, and by its acidity and selective antiseptic property arrests their further development. Given such a physiological antiseptic, if not possibly germicidal lubricant of the vagina, with the additional provisions of its walls being constantly in apposition and a plug of mucus in the cervix, it is fair to conclude that a woman rarely, if ever, becomes infected except that such infection is conveyed from without, either by the doctor, the nurse, or by the vaginal secretions having first been washed away by means of douches.

Bacteriology has contributed so liberally to medical science that it is scarcely possible to find a doctor of medicine who does not thoroughly cleanse his hands be-

fore attempting to make a vaginal examination; yet almost as rare as this is it to find an accoucheur who first cleanses thoroughly the external genitalia and adjacent parts of the patient. While asepsis has markedly lessened the percentage of septic cases after delivery, it is unfair to expect a hand perfectly free from germs, after proper cleansing, to pass over unclean skin and hair—two of the common sources from which infection may come—and yet carry no micro-organisms with it into the vagina, cervix, or uterus.

The question of when and when not to douche before delivery of the child is one deserving of consideration. Various authors advise douching where leucorrhœa is pronounced; others, where it is alkaline in reaction or highly irritating; others, where it contains pathogenic bacteria, or where unclean instruments have been introduced into the vagina, as in abortion.

A profuse discharge is no indication whatever for vaginal douching, except that bacteriological examination has shown such discharge to contain virulent pathogenic organisms. I have repeatedly seen a marked leucorrhœa continue for weeks or even months, yet repeated bacteriological examinations failed to detect the presence of any pathogenic bacteria. When the discharge is alkaline, or faintly acid, the varieties of bacteria found are many; yet it is likewise rare to find organisms pathogenic in character. Kronig, in about two hundred examinations, decides that the vagina contains no pathogenic organisms except those of gonorrhœa and the thrush fungus. He further found that if, an hour after the infection of the vagina, an antiseptic douche of lysol were administered, the micro-organisms were not destroyed, and that it took the vaginal secretions from nineteen to thirty-six hours to destroy these microbes; but when no douche was given, the same bacteria would disappear in from eleven to twenty hours.

Doderlein in a hundred and ninety-five examinations found streptococci in eight. However, he was unable to show that this organism was pathogenic in but five cases. Williams, in a report of the study of ninety-two cases, in connection with a general survey of the literature, agrees with Kronig that "the vaginal secretion does not contain the usual pathogenic cocci," having found the *Staphylococcus epidermidis albus* twice. Kelly, in his late work on gynecology, states: "If staphylococci alone are present, especially the comparatively harmless citreus, albus, or epidermidis albus, the danger to the health of the patient is much less than in the case of the streptococcus, which tends to produce general infection."

Walthard found streptococci in twenty-seven out of a hundred cases examined, yet he was unable to demonstrate any virulence of these organisms. Inoculations on animals gave no results, except that a certain part of the animal was first reduced in vitality, in which case he was able to produce abscesses. Walthard draws

the following conclusions: "The virulence of vaginal streptococci of a pregnant woman, not examined for some time, is equal to that of the streptococci that live upon other mucous membranes, or in their secretions. In other words, the vaginal streptococci are not virulent, and behave as saprophytes upon healthy tissue."

Gonorrhœa may be either urethral or cervical. Since gonorrhœal pus causes no irritation to the vaginal walls, even when kept in direct contact with them for twenty-four hours, there is little necessity for douching the vagina, a surface already immune. If the urethra alone is affected, the douche would have a tendency to remove the normal vaginal secretions, and thereby allow the gonococcus to make its way to the cervix unmolested. Studying a large number of cases in the venereal wards of the Philadelphia Hospital, I noticed that a large percentage of the cases showed involvement of the cervix uteri. A more careful study proved that patients who had not taken vaginal douches were most likely to show only involvement of the urethra; while fully four fifths of such patients showed involvement of the cervix in from one to two weeks after admission. (Vaginal douches were given every morning.) It has been my fortune to follow several cases in which gonorrhœa developed during the period of gestation, in one of which there was pronounced vaginitis; yet in all of these cases there was nothing abnormal during delivery or the puerperal state, nor was there any infection of the children. Bacteriological examination alone can determine whether or not a leucorrhœa is gonorrhœal in character, and the fact must not be lost sight of that diplococci, which are found in the pus corpuscles clinging to the epithelia, giving the same reaction to stains (do not stain by Gram's method), are occasionally met with. The difficulty with which the gonococcus is grown on ordinary media is probably the true differential point. The question of irritation and the introduction of instruments is one to be left entirely to the judgment of the physician in charge. "It has been clearly demonstrated that the injection of an antiseptic fluid into the vagina will not destroy pathogenic germs there, and will rob the woman to a certain extent of the safeguards that Nature provides for her against infection" (Hirst).

The objections to the use of ante-partum douches will in a great measure hold true in cases after the delivery of the child. However, a post-partum douche, if carried into the uterus, may be of service in stimulating that organ to contract, and thereby arrest hemorrhage. It may also be of service in the removal of small particles of placenta and membranes, and to remove toxins from the uterus after the symptoms of sepsis have developed. The giving of a uterine douche, after the hand has been introduced into the uterus, or after the application of forceps, is an unnecessary procedure, as it can do no good.

Where a uterus has once become infected a uterine douche does not even attempt to remove the bacteria.

It simply washes away the toxins and thereby prevents further absorption into the general system, giving the patient relief, and allowing her to gain sufficient vitality to prevent the further development of the micro-organisms already well imbedded in the uterine mucosa. Not only is this true of douching, but of curettement. I have repeatedly made cultures from the gauze removed from a uterus in from twelve to twenty-four hours after a curettement, and have never failed to find the same bacteria that were present at the onset of the symptoms; however, cover-slip preparations always showed a diminution and occasionally an absence of these organisms; and I have found a pure culture of the *Staphylococcus pyogenes albus* from the cervical discharge forty-eight hours after the pulse and temperature were normal.

To summarize:

1. A profuse leucorrhœa during the latter months of pregnancy is no indication for vaginal douching.
2. The chemical reaction of a discharge has but slight effect upon its antiseptic powers.
3. The vaginal secretions of pregnant women rarely, if ever, contain pathogenic germs except gonococci.
4. Vaginal douches favor the development of cervical gonorrhœa and puerperal sepsis.
5. The vaginal secretions may contain streptococci, staphylococci, diplococci, and bacilli, all of which may be non-pathogenic.
6. A discharge from the cervix may show the presence of pathogenic bacteria after all other symptoms of sepsis have disappeared.

PNEUMONECTOMY.

THE FUTURE TREATMENT OF INCIPIENT PULMONARY TUBERCULOSIS.

By JOHN S. PYLE, M.D., LL.B.,

TOLEDO, OHIO

THE subject of this paper states an opinion which I have held for some time, the propriety of which, I believe, will be established in the near future. The high death-rate and the unsuccessful medical treatment of pulmonary consumption are my apology for wishing to place this disease, in its incipient stage, in the category of surgical ailments. I am surprised that this has not been attempted, as the results from surgical interference in tuberculous affections of the joints, lymphatics, and abdomen have been so gratifying that one would naturally expect, reasoning from analogy, a desire to apply a similar treatment to the same affection wherever located. The lungs, however, would seem to offer a good field, for the reason that our diagnostic resources are such that the disease could be brought under effectual treatment before it had become widely disseminated. Most cases of pulmonary tuberculosis begin with a single focal point of infection, and I reason, were

we to secure this by a well-directed pneumonectomy, there is every reason to believe that this form of treatment would prove absolutely curative. From experiments which I have made on animals, I am satisfied that excision of diseased lung is not only a possibility, but comparatively easy of accomplishment. I commenced my studies on the subject in question in the fall of 1894 and continued them through the winter of 1894 and 1895. Dogs were used for the experimental work. My observations at the time were interrupted, and I am sorry that I have been unable thus far to put the knowledge gained into execution on the human subject. However, I hope to do this before a great while, and will content myself for the present in submitting the most important points developed as a result of my experiments.

I was anxious first to learn the requirements of success in making a pneumonectomy, believing that when this was accomplished the way was clear for successful work upon diseased lungs. No preference was given to animals previously inoculated with tuberculous material, as the knowledge to be gained was of a technical nature and could be gained equally as well upon the healthy animal. First, in regard to the precautionary measures, the same observations apply here as in other surgical work. Those relating to cleanliness must be insisted upon, as the pleura and lung tissue may be a little less resistant to the lower forms of surgical infection than some of the tissues of which we are more familiar. A cautery is necessary, and preference is given to good strong silkworm gut as the material for ligating the mass to be excised. A very important point is the location of the opening incision. It should be remembered that when the pleural cavity is opened, air enters and the lung collapses, leaving the thoracic cavity almost empty. The extreme points, the apex and the tip of the lower lobe of the lung are drawn so far away from corresponding points on the thoracic wall that if an opening is made immediately over the point where the excision is to take place, the lung will be found not available. Therefore it is better, when attempting the removal of either apex, to make the initial incision over and in line with the fourth rib, and, in any case, not higher than the third. This being determined, commence the incision near the outer margin of the sternum and carry it outwardly far enough to allow the easy introduction of the hand into the pleural cavity for the purpose of examining and withdrawing the desired lung. The rib should be removed next, and, in doing so, avoid the needless opening of the pleural cavity, as the introduction of air causes severe dyspnea, which may just as well be postponed until preparations are complete to hurry the conclusion of the operation. The costal end should be divided first, and the rib carefully peeled from its osseous and muscular coverings. Of course, it is understood that the area of the diseased lung should be clearly in mind before beginning the

operation. Upon opening the pleural cavity, the lung should be seized and engaged in the wound so as to obstruct the ingress of air, which will be found materially to lessen the labored breathing and afford the patient the needed oxygen. The amount of lung to be removed having been determined, a ligature, preferably of silkworm gut, should be thrown around the base of the mass, and drawn so tight that the bronchi and lung tissue are forced into a solid mass. A narrow-bladed clamp should then be applied external to the ligature and the engaged piece of lung removed with the cautery. After searing, the clamp should be removed and the disengaged stump dropped into the pleural cavity without further attention. The edges of the pleura should now be stitched together by means of a continuous suture and the superficial wound closed in like manner. Collodion makes an indispensable dressing for the purpose of hermetically sealing the opening into the pleural cavity. Labored breathing will be pronounced for the first twenty-four hours, but afterward will subside, due to the absorption of air imprisoned in the pleural cavity. It would be possible to remove this air by means of an air pump, but I am of the opinion that there is an advantage in a partial collapse of the lung in securing rest to the amputated part during repair. This is certainly favorable to the ligature securing the stump and prevents adhesion between the visceral and parietal pleura.

One of the great dangers in the operation is death from hemorrhage. This may occur from an accidental slipping of the ligature or from extravasation of blood in the air cells and lung tissue. This, however, will not occur if the ligature is properly applied. It is necessary to avoid puncturing the lung, as a fatal hemorrhage may follow the opening of a vessel. To avoid this accident, a better way is to throw the ligature around the entire mass and secure it by a proper knot. It should be drawn very tight. Pneumonia, I believe, will rarely occur where perfect surgical cleanliness is observed. When it does, I am satisfied it is due to defective precautions. I have made in all about thirty pneumonectomies, and was surprised, on re-examining the cases after some two to four weeks' convalescence, to find that I had the greatest difficulty in locating the site of my first operation. In many instances no stump remained. The lung filled the pleural cavity as though none had been removed, and this was true in all cases except those where an entire lung had been extirpated. In the latter cases the corresponding side of the thorax was destroyed through lack of equalizing the atmospheric pressure, but where a portion of lung was left to occupy the pleural cavity the air cells would undergo dilatation and conform to the thoracic walls. A lobe or more could be easily removed without altering in the least the contour of the chest.

The effect of the surgical work upon the animal differed in no way from the ordinary operation of equal

gravity elsewhere. I did not attempt a scientific demonstration of the effect upon the vasomotor nervous system, and will have to be content in supplementing this with speaking comparatively. Abdominal operations, I believe, affect the nervous system more seriously than operations upon the pleural cavity. This may be accounted for on the ground of exposure and disturbance to the splanchnic and other large ganglionic centres. In operations upon the pleural cavity or lung there is no such complicated system exposed to irritating influences. The respiratory plexus is, of course, involved, but in no instance did I witness any disturbance from this source. The same was also true of the cardiac movements. The convalescence, where the work was satisfactorily accomplished, was uneventful, and the animals partook of food with a relish the second day after their operations. With these favorable observations upon the dog, I can see no reason why we should expect any worse results upon man. A forced respiratory apparatus will doubtless be necessary in undertaking the successful work upon man. We should be provided with every appliance to sustain respiration artificially. Here would be a case where a trial operation upon a capital criminal would be of incalculable benefit. Could we obtain such practical information, it would immediately put us in possession of knowledge that could be turned to good account. However, we hope that a favorable opportunity will present itself and we shall soon be able to verify our views.

2128 ASHLAND AVENUE.

MEDICAL GYNÆCOLOGY:

OR, THE RELATION OF
VITAL DEBILITY AND PASSIVE CONGESTION
TO DISEASES OF WOMEN.

By EUGENE COLEMAN SAVIDGE, M.D.,

ATTENDING GYNÆCOLOGIST TO ST. MARK'S HOSPITAL;
ASSISTANT GYNÆCOLOGIST TO BOW-DOYER HOSPITAL;
OUT-PATIENT DEPARTMENT.

GYNÆCOLOGY has evolved rapidly. There are probably more specialists in gynecology than in any other single branch of medicine. There are probably more patients for these specialists than for specialists in any other line. One wonders what humanity did before the specialty began its evolution.

A prominent gynecologist has recently lifted the specialty from pelvic limitations up as far as appendix and kidney, and has reported observations which merit the serious discussion of the profession. I refer to the series of papers by Dr. Edebohls, of New York, the last of which appeared in the *Medical Record* of March 11, 1899, and was entitled *The Relations of Movable Kidney and Appendicitis to Each Other and to the Practice of Modern Gynecology*.

A New Note in Gynecology.—Considering this a step forward in the steadily evolving specialty, I venture a discussion of the subject. The new thesis is:

1. The local treatment of the general practitioner years ago did not give a great degree of therapeutic success.

2. The numerous failures led men to surgery—that is, major pelvic surgery, such as ranged ten years ago. This was a step forward, yet candid men had to confess that in many cases symptoms persisted after pelvic surgery had done its utmost.

3. The frequent failures of pelvic surgery to give relief, after the removal of everything possible, led earnest men to seek further.

A number of writers thereupon began calling attention to the frequent connection between downward displacement of the abdominal viscera and malpositions of the uterus. Dr. Edebohls has added the following observations: One fifth of *all* women have movable kidney or kidneys, though only one fifth of those afflicted (or one twenty-fifth of *all* women) have symptoms therefrom. Of those with symptom-producing displacement nearly all have appendicitis accompanying, as a result of hampered return circulation by indirect pressure of the displaced kidney on the superior mesenteric vein. Dr. Edebohls's thesis ends at this level, and his experience is that both appendectomy and nephropexy must be added to the former pelvic operations to restore such patients to perfect health; and that with these two added operations "gynecology has finally approached the ideal of an exact science."

Specific Cases.—We can grasp the subject better by specifying the class of cases belonging to it. Obviously vaginitis and other exclusively local matters will not fall under the list of failures from "local treatment." On the other hand, we can not charge failure to major pelvic surgery in such conditions as malignant growths, the rupture of a pus sac or a blood-vessel, or the torsion of a pedicle, or the rapid absorption of poison from an infected centre, or the strangulation of an intestine or excretory duct by pressure or otherwise, or ectopic gestation. If these grave cases are complicated with kidney or appendix trouble, the routine examination which discloses the trouble is a forward step in technique; and the correction of the trouble is so simple and easy and necessary as to preclude all debate.

This leaves for discussion an entirely distinct class of cases, viz., retrodeviation of the uterus, and what I have classified in a recent paper as "the less urgent cases of swollen and tender tubes, cystic ovaries, etc." I continue the quotation:

"These are the cases which walk about with slight disability, hope for a miracle from an operation (upon the pelvic organs), and spread distrust of the surgeon when they find it does not come. . . . In the evolution of gynecology many cases of passive congestion and muscular debility have been treated by abdominal section, and have been helped by the operation. Patients of this class have consulted the gynecologist month after month for a pelvic soreness that 'treatment' only temporarily assuages, and finally in discouragement

have consented to 'have something done'—that something meaning an abdominal section.

"In the *Medical Record* of March 19, 1898, the writer has discussed this neglected subject of passive congestion of the pelvic and abdominal organs. It comprises a congestion—almost an erectile condition—of ovaries, tubes, rectal veins, liver, spleen, kidneys (and appendix), and the soreness it brings is entirely analogous with the pain in the breasts near the menstrual epoch. Some women have breasts as sore as boils at this period—yet breasts have not been made the subject of operative furore on this account. This pelvic condition goes to form the diagnosis of 'salpingo-oophoritis.'"

Partial Failure of Orthodox Methods.—Bearing firmly in mind the specific class of cases under consideration, few medical men will disagree with the first postulate of the new thesis: "Local treatment" has not given satisfactory results; and, moreover, under the second postulate, the final resource of pelvic surgery has frequently left the poor patients with veins of the leg, rectal veins, appendix, kidneys, liver, and spleen as congested and as sore as before. Every operator has had this unhappy experience.

As to the third postulate: Aside from the credence due to responsible testimony, it is perfectly in accord with reason to believe that the added operations will relieve the congested parts operated upon. More especially is this true in cases of retrodeviation of the uterus, where the uterine displacement is only a later manifestation of the general enteroptosis. This view of retrodeviation (see *New York Medical Journal*, December 25, 1897) brought me some criticism when first advanced; and I therefore welcome this corroborative testimony from so high a quarter. My own observations, then, lead me to accept fully the statistics regarding the prevalence of these subject maladies in women living in our cities.

Even those of us who urge that gynecology is not all surgery, but has a feebly developed medical side, will be disposed to admit that surgery is the proper indication with patients who are improvident, self-neglectful, or not intelligent enough to weigh the alternative of medical treatment, or those who prefer surgery after considering both sides. Surgery, in these cases, is the strait-jacket where the moral suasion of medical treatment would fail.

Dissent.—But, admitting all this, I do file a protest that gynecology is more than surgery. Granting the prevalence of the condition, and granting the surgeon's power to correct it, it is still within the province of gynecology to seek the cause of so frequent an affliction. It is still non-surgical gynecology which guards against the condition. Prophylaxis in gynecology—a new field within the specialty—may render some surgery unnecessary; but think of the many favorite methods of treating small-pox made useless by vaccination!

Important to Seek the Cause.—The earnest conviction which I have repeatedly expressed is that the cause

of enteroptosis, displaced kidneys, retrodeviation of the womb, and an engorged venous system in women will be found in vital and muscular debility. Dr. Edebohl's says: "The one thing settled about the etiology of movable kidney is that it is due to a *relaxation and stretching* (Italics mine) of the lamina fibrosa of the renal adipose capsule." It is self-evident that relaxation and stretching would not occur in those muscularly and vitally fit. And is it not the gynecologist's province to maintain this "fit" condition in women? If the gynecologist can correct tendencies toward this unfitness and thereby avoid abdominal section, is not this non-surgical function as important as that of the surgeon who can only repair by mutilation?

Increased Venous Pressure and the Special Organ.—For example, the return blood current in the nose is hampered and we have a rhinitis; in the larynx, and we have laryngitis; in the bronchial tubes, bronchitis; in the spleen, splenitis; in the liver, hepatitis; in the appendix by the indirect pressure of a misplaced kidney on the superior mesenteric vein, and we have appendicitis. The infection follows the congestion, as a rule. Now, is it far-fetched to call a rhinitis in part an aggregate phlebitis, in that innumerable small veins become engorged and inflamed? Is not the same condition to be found in the veins and their *vasa vasorum*, down the leg, in the rectum, up the sides of the pelvis, and around the appendix itself? The relation between a debility of some sort and this hampered return blood current is evident. It is well known that increased blood pressure impairs the resistance of cellular life.

The whole subject of lithæmia, renal and cardiac—and, indeed, bronchial and laryngeal—involvement in passive congestion is simply named in passing.

Advancing Gynecological Views.—But I urge special attention to the steadily advancing conception of the gynecologists from (1) the idea that pelvic soreness was a cellulitis, (2) to the idea that it was almost exclusively an infection through the womb along the tubes, (3) to this new and truer idea that the congestion often comes first, and then follows an infection from the "resident germ"; and that this congestion is not limited to organs in the pelvis only, but extends from the plantar arch to the veins of the diploë. Recall for a moment puerperal eclampsia, puerperal insanity, the insanity of the menopause, the insanity in some post-operative cases, and the fact that the majority of hysterical and neurological cases are feminine. Congestion is the one known underlying fact in these cases.

(Of course, infection precedes congestion in all cases of contagion or inoculation.)

Some Spectacular Effects.—When these poor women return, aching after pelvic operations, one can frequently be as spectacular as the charlatan by calling their attention to their sore veins at the ankle, behind the knee, in the groin, in the rectum, up the sides of the pelvis, in the region of the appendix and over the liver and

spleen, or at one or more of these points. They draw immediate inference: they were operated upon unnecessarily. This should make a conscientious man—knowing how gynaecology has felt its way along, step by step—hasten to defend the operation. I have toned up the veins of many a post-operative case, but have never allowed such an inference to be uttered before me without earnest protest.

But if, by repeated success in ailing cases that have already been operated upon, and cases that have only contemplated operation, one has found that trouble in specific organs is often but part of a general condition, he is perfectly justified in saying to patients who dread abdominal surgery, "That is not alone your trouble; but here and here and here."

Even those who must do surgery to live will admit that if a tendency toward a deplorable condition can be recognized before an operation is justifiable, it is our duty to save the patient from the surgical cataract roaring in the distance.

Great Benefit from the Rest in Bed.—I debate whether much of the benefit from surgery—bear in mind all through this discussion the restricted class of cases—is not due to the rest in bed and the special care given an invalid after an operation, especially in cases of retro-deviation of the womb.

I cite in support the many successes of the Weir-Mitchell rest-cure régime.

What can be done without the Knife.—When by régime—but not by "local treatment"—you can take off fifty pounds in weight or put on forty; when you can decrease the size of a dilated heart, as proved by the skiagraph; when you can make the flabby solid of flesh, increase chest expansion, clear up brick-dust urine, stop palpitation, quiet borborygmus; change the color of the skin, the lustre of the eye, the strength of the heart's impulse; tone up various varieties of ptosis, remove the symptoms of retro-deviation, and ease the aching venous system—when all this can be done without the knife (remember again the class of cases), you are justified in protesting that there is an important medical side to gynaecology. And especially when all this has frequently to be done after women have been as completely eviscerated as possible.

What Women did before Gynaecology.—When, therefore, one wonders what women did before the specialty began its evolution, one can consider that the requirements of modern life have entailed upon women tendencies that have made the specialty necessary. Former generations, living more in the open air, had greater muscular power and probably required less abdominal surgery.

Discussions upon this new step in gynaecology are valuable even if some of us are on the wrong side, for "truth comes more readily from error than from chaos."

Therapeutical Notes.

Injection for Gonorrhœa in Men.—The *Journal des praticiens* for May 6th gives the following formula:

R Gallobromol 60 grains;
Distilled water, each 1.500 "
Glycerin,

M.

Sodium Cinnamylate in Tuberculous Diseases.—Dr. Lowzki (*Pract.*, 1899, No. 1; *Deutsche Medizinisch-Zeitung*, April 17th) has used a two-and-a-half-per-cent. solution subcutaneously in eight cases. He gives an injection twice a week, injecting at first as much of the solution as it takes to reach to the first mark on a Pravaz syringe, and increasing it gradually to six times that amount. The patient pursues his ordinary occupation during the treatment. The night sweats diminish gradually and finally disappear altogether. Almost all the patients gain flesh. The number of tubercle bacilli in the sputum is reduced—in one case they disappeared entirely—but they generally return subsequently, although in insignificant numbers. Purulent expectoration becomes mucous. The cough is materially mitigated. If the portion of lung tissue affected is small, and there is only moderate fever, improvement, both subjective and objective, is comparatively speedy. In hasty consumption the remedy does no good.

An Antiseptic Dentifrice.—*Lyon médical* for April 9th cites the following formula from the *Bulletin de pharmacie de Lyon* for March:

R Salol 300 parts;
Alcohol 15,000 "
Oil of star-anise, each 50 "
Oil of geranium, each 50 "
Oil of mint 1 part.

M.

A Pill for Gouty Migraine.—Dr. R. Bommier (*Nord médical*, April 15th) recommends this pill:

R Quinine valerianate 30 grains;
Extract of colchicum 9 "
Extract of digitalis 6 "
Powdered acornit leaves 3 "

M. Divide into twenty pills. One to be taken an hour before dinner, for five days in the week, with a glass of lithia water.

A Liniment for Hæmorrhoids.—The *Gazette hebdomadaire de médecine et de chirurgie* for April 20th credits the following formula to Adler:

R Fluid extract of hamamelis,
Fluid extract of hydrastis, each, 16 parts;
Compound tincture of benzoin,
Tincture of belladonna 4 "
Five-per-cent. solution of carbolic
and in olive oil 32 "
M. To be applied two or three times a day

For Chloasma. According to the *Riforma medica* for May 5th, Kaposi recommends:

R Naphthol 30 grains;
Glycerin 15 "
Tincture of green soap 750 "

M.

To be applied locally twice daily

NEW YORK, SATURDAY, JUNE 10, 1899.

THE COLUMBUS MEETINGS.

YEAR after year there are more and more satellites to the annual meetings of the American Medical Association. This week, in Columbus, they included meetings of the American Academy of Medicine, the Association of American Medical Editors, the National Confederation of State Medical Examining and Licensing Boards, and the Association of American Medical Colleges. The meetings were all well attended, as was to be expected. That of the American Medical Association was noteworthy, apart from the great number in attendance, for the excellence of the formal addresses. Recognizing the fact that these addresses would sufficiently cover the ground of purely scientific communications, so far as addresses were concerned, the president, Dr. Mathews, wisely read what he himself denominated a "message," rather than an address on any one medical topic, although he dealt most forcibly with plans for restricting the prevalence of tuberculous and syphilitic disease.

It is satisfactory to find that Dr. Mathews favors a "local habitation" for the association, and we have no fault to find with his choice of Washington as the locality, although we have recently favored a number of central cities as places in which the association should meet in turn. Dr. Mathews gives excellent reasons for preferring Washington, and it is undeniable that that city has unexcelled facilities for disposing of visitors. Another matter handled very dextrously by the president was the chronic difficulty over the permanent secretaryship. He suggests that the editor of the association's *Journal* should be, *ex officio*, the secretary. No doubt such an arrangement would conduce powerfully to the best conduct of the affairs of both the association and its *Journal*. In our opinion, the president properly deprecates the clinics, dinners, etc., that now lure so many members away from the sessions. We trust that Dr. Mathews's rebuke to the Antivaccinationists may prove of some avail, but they are a stiff-necked lot, hide-bound by their fad. As a whole, the address was scholarly and eminently practical, and we commend it to all our readers.

SUMMER HEAT AND THE SUMMER DIARRHŒA OF INFANTS.

THAT the influence of summer heat—an undeniable factor in the production of the summer diarrhœa of infants—has often been misinterpreted there can be no doubt. Some who recognize most distinctly that the heat of summer operates more particularly in the ætiology of infantile diarrhœa by favoring deleterious changes in the milk on which the infant subsists can not, nevertheless, overlook altogether the old idea that the summer diarrhœa of infants is a form of "thermic fever" with a special intestinal manifestation. Among these is Dr. Stawell, honorary physician to the outpatient department of the Children's Hospital, Melbourne (*Intercolonial Medical Journal*, March). However, Dr. Stawell agrees with all special observers that summer heat "must be classed only as a remote, predisposing, though very potent factor in the causation of summer diarrhœa." He thinks that wherever the general winter temperature is comparatively high, and the child is acclimatized to it, a summer temperature correspondingly higher than that elsewhere capable of giving rise to a decided increase of mortality from summer diarrhœa is required to produce the same effect. For example, in Queensland, he says, the child gets acclimatized to a high winter temperature, "and must be exposed to a correspondingly higher temperature in summer than the child in Melbourne before diarrhœa comes on." Further, he thinks that if the power of resistance in the individual is very great, "even decomposing food may produce no deadly result; older children, for instance, can drink obviously stale milk without suffering, calves can digest sour milk, and pigs fatten on putrid food."

Nevertheless, Dr. Stawell is a thorough adherent of the doctrine that summer diarrhœa is due to septic changes in the milk taken by the infant. "Broadly speaking," he remarks, "no completely breast-fed infants die from 'summer diarrhœa,'" and this statement he supports by citations of the statistics given by Dr. L. Emmett Holt. In his own hospital experience Dr. Stawell has not met with a single fatal case of summer diarrhœa in an exclusively breast-fed infant, and he believes his colleagues' experience has been the same. "In the country," he says, "there is no summer diarrhœa, or, to put the matter in another way, if the mother of an artificially fed infant has a cow of her own which can be milked twice daily, the summer heat will rarely help to induce intestinal irritation in the infant, and the milk is, of course, given fresh, before heat has induced changes in it." Dr. Stawell's observations in the

Southern Hemisphere are certainly confirmatory of the most trustworthy reports on the subject that we have from physicians of our own quarter of the world, and they are deserving of close attention.

"PARESIS HALL."

WHEN a legislative commission sets about investigating the management of the city of New York, we must presume that it is quite within its sphere to bring out testimony bearing upon matters illustrative rather of the depravity of certain of the inhabitants than of the essentials of municipal government. We are not saying that to demonstrate that vice flourishes openly in the city is not to show laxity or favoritism on the part of the officers of the law, but we fear that such demonstrations can do no good further than to stir up a temporary feeling of horror among the good people of the State that may lead to further repressive legislation, a two-edged sword susceptible of being put to base uses by first one and then the other of the principal political parties, accordingly as the one or the other is in the ascendant for the time being and feels reasonably certain of so continuing.

But, granting that it is judicious to lay bare the rottenness of such resorts as Paresis Hall—a place that seems to be well deserving of its name—there next arises the question of whether or not it is productive of good rather than evil to allow the portraiture to go before the general public. Paresis Hall, it seems, is a resort for certain vicious male individuals who are euphemistically called degenerates. The very existence of such characters is unknown to the better part of the people, or was until the Mazet commission made its inquiry into the conduct of Paresis Hall. In our opinion it had better have remained unknown. It is to be feared that there are multitudes of young men, either resident in New York or visiting here, who will be led by sheer curiosity to take a look at the place or at some other one of the same sort, for we are informed that it is not the only one of its kind, and that access to it, and presumably to the others, is easy to any man. The moral effect must be little short of disastrous. We are aware that the commission can not carry on Star Chamber proceedings; its inquisition must be open to the public if it is to command the people's confidence. The responsibility, therefore, rests with the press. The "yellow" papers, of course, could not be expected to restrain themselves from serving up this horror to their readers, a class, fortunately, which they are incapable of making much worse; but it was to be hoped that the newspapers that are commonly regarded as

"clean" would desist from mentioning such matters, or at least would refer to them only in the most general terms. We regret to see, however, that they have not all followed this wholesome course. Familiarity with vice, even by hearsay, is not edifying to any community.

THE LARYNGOSCOPICAL DIAGNOSIS OF SEX.

WHAT have been felicitously termed the "secondary sexual characteristics" by Bland Sutton seem to be coming more and more into recognition as of importance in medicine. Among them is the voice, and the subject of The Voice in Diagnosis has lately been handled by Dr. Alexander J. C. Skene in a masterly manner in a paper which we publish in this issue. The respective qualities of the masculine and feminine voice depend upon anatomical differences in the larynx in the two sexes. On the strength of a knowledge of these differences Dr. E. Berthold (*Archiv für Laryngologie*, ix, 1, 1899; *Laryngoscope*, May) recently made bold, as the result of a laryngoscopic examination, to question the reputed sex of a person who came to him dressed as a woman. He discovered that the vocal cords were broader and longer than those of a woman, and an examination showed that his suspicion was well founded; the individual had the genitals of the male, although they were misshapen. Subsequently a Röntgen-ray examination showed that the thyroid cartilage had become ossified to an extent that takes place only in the male.

THE PANCREAS AND THE TUBERCLE BACILLUS.

It is probable that the treatment of pulmonary consumption with pancreatic extract, that had some vogue a few years ago, owed whatever efficacy it may have had to its promotion of the digestion of fatty food. Perhaps, however, the pancreas may be made use of more directly in tuberculous disease, if we may draw an inference from certain experiments made by M. P. Carnot (*Thèse de Paris*, 1898; *Centralblatt für innere Medizin*, May 13, 1899), who finds, among other things, that tubercle bacilli injected into the gland, if not in too large quantities, are destroyed.

"EMBALMED" MILK.

THE newspapers report that the people of Omaha are afflicted with a milk supply so altered by the addition of preservatives that the sanitary authorities have felt called upon to warn the citizens of the great danger of feeding infants with the milk. We are not told what chemicals have been used, but there can be no excuse for the use of any as preservatives of the milk provided for a city like Omaha.

THE ESKIMO BRAIN.

AT the recent meeting of the American Medico-psychological Association Dr. Halden presented the results of an examination of the brain of an adult Eskimo, one of several free specimens by Mr. Peary some time ago. The author is reported to have stated that the Eskimo brain was heavier and larger than the average brain of the European of the same stature, the parts particularly developed being those containing

the centres for sight, hearing, and smell. Opportunities for examining the Eskimo brain are not common, but the subject offers an inviting field for research.

A CHANCRE OF THE CONJUNCTIVA.

THE conjunctiva would seem a very unlikely place to find a primary syphilitic sore, yet Dr. E. C. Ellett records, in the *Ophthalmic Record* for June, the case of a man, twenty-four years of age, who had an inflammatory affection of the right eye of about four days' duration, presenting externally the appearance of a moderate-sized chalazion situated at the inner extremity of the upper lid. On everting the lid an ulcer rolled into view. The edges were elevated and whiter than the centre, and the base was firm and unyielding. There was a moderate amount of secretion, no pain, but a stiff, sore feeling, and the surrounding ocular and palpebral conjunctiva was injected. The preauricular gland on the right side was much enlarged and quite hard, and the superficial cervical glands in front of and behind the sterno-mastoid as well. There was no history of possible infection, except that he had often washed his face and hands in hotel lavatories and dried them on the public towel. The diagnosis seemed to be sufficiently plain, and was confirmed by the fact that four weeks from the day of the beginning of the eye trouble a syphilitic roseola appeared on his body. This eruption was quite typical, and there was at this time general adenopathy. The primary sore had hardly changed its appearance. Considering how widespread venereal diseases are, there is undoubtedly a source of danger in the common use of roller towels in public lavatories, which needs as wide recognition as the danger of public drinking cups, etc.

SONG BIRDS AS A SOURCE OF PHTHISIS.

DR. TUCKER WISE (*Lancet*, May 20th) calls attention to the fact that among cage birds, pigeons, and poultry tuberculosis is a common disease, and his attention has been directed to the number of phthisical patients who have lived in contact with diseased canaries and other feathered pets. The dust and filth of the cage can be conveyed by flies to food, and some people even court infection by caressing the birds and allowing them to place their beaks in contact with the lips. Dr. Wise records ten cases in which infection appears to have been derived through birds. He says: "Although doubts have been expressed regarding the identity of avian tuberculosis with that of mammals, Friedberger and Fröhner mention that the more recent investigations of Cadiot, Gilbert, Roger, Fischl, Courmont, and others tend to show that these two forms of tuberculosis are produced by the same species of bacilli, although by different varieties, the differences between them having been produced by differences in their respective modes of nutrition." Dr. Wise's article sounds a warning note to which heed may well be paid for the purpose of further investigation.

THE UNACKNOWLEDGED CLIPPING HABIT.

WE must again call attention to the fact that we are dropping from our exchange list journals which we detect in wholesale clipping, without acknowledgment, from our columns. Accidents, of course, will occasionally occur, but instances are often so flagrant, as in the

case of one journal which we have dropped this month for five such offenses in one number, that they can be only intentional. We are interested in the maintenance of that system of journalistic courtesy which is willing to place the free use of its material for the public good in the hands of editorial *confreires*. But that courtesy, like all others, deserves the acknowledgment which we ourselves consistently endeavor to give, and which we certainly expect.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending June 3, 1899:

DISEASES.	Week ending May 27.		Week ending June 3.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	58	4	13	5
Scarlet fever.....	212	17	214	14
Cerebro-spinal meningitis....	0	7	0	13
Measles.....	404	16	420	19
Diphtheria.....	238	31	249	46
Croup.....	12	4	7	10
Tuberculosis.....	169	141	142	139
Small pox.....	12	3	11	2
Chicken-pox.....	34	0	36	0

Marine-Hospital Service Medical Supplies.—The following circular letter from the office of the supervising surgeon-general, Marine-Hospital Service, dated Washington, June 3, 1899, has been addressed to commissioned officers, acting assistant surgeons, and others concerned:

You are hereby notified that so much of the work of the purveying division of this bureau as pertains to the issuing of medical and other supplies to the various stations under the control of this service has been transferred to New York city, where a purveying depot has been established at No. 378 Washington Street, in the borough of Manhattan. All requisitions for supplies will be addressed as heretofore to this office for approval. Officers in command of stations are requested to withhold, until the beginning of the ensuing fiscal year, requisitions for supplies, except in cases of emergency, in order to reduce the work of the purveying depot to a minimum during its installation.

Contractors for supplies are also notified of this change of address for freight and other shipments. The official address for freight will be "Medical Purveyor, United States Marine-Hospital Service, 378 Washington Street, New York city," and articles hereafter ordered for the use of this service must be shipped in accordance therewith.

[Signed.]

WALTER WYMAN,

Surgeon-General, Marine-Hospital Service.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, June 3d, Dr. James Moores Ball was to read a paper on the Removal of the Superior Cervical Ganglion for Glaucoma, with report of a case. The paper was to be discussed by Dr. Willard Bartlett and Dr. E. C. Renaud and others. Dr. Robert Barclay was to make A Report of Actual Cases Demonstrating the Relief, by Modern Methods, of Patients Hopelessly Afflicted for Many Years with Deafness from Catarrh, Running Ears, Low Speaking Voice,

Dizziness, Noises in the Head and Ears, Worse Hearing in Quiet Places, Aural Distress, etc.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the supervising surgeon-general during the week ending June 3, 1899:

Small pox.—United States.

Los Angeles, Cal.	May 27	3 cases.
San Francisco, Cal.	May 19	1 case.
Soldier in Army Hospital.		
Washington, D. C.	May 20	1 death.
Jacksonville, Fla.	May 27	1 case.
West Tampa, City, Fla.	May 20	3 cases.
Savannah, Ga.	May 9-29	13 "
Emporia, Kan.	May 20	3 "
Frankfort, Ky.	May 23	2 "
Louisville, Ky.	May 23 to date	475 " 4 deaths.
Mt. Sterling, Ky.	May 23 to date	2 "
Morgan City, La.	May 21	7 "
New Orleans, La.	May 22-29	9 "
Fall River, Mass.	May 28	10 "
Swampscott, Mass.	May 31	20 " 1 death.
St. Louis, Mo.	May 12-22	12 "
St. Louis, Mo.	May 22-29	4 "
Omaha, Neb.	May 29	1 case.
New York, N. Y.	May 29	3 deaths.
Cleveland, Ohio	May 15-22	13 cases.
Massillon, Ohio.	May 27	1 case.
Johnstown, Pa.	May 15-22	1 "
Philadelphia, Pa.	May 27	29 cases.
Pittsburgh, Pa.	May 26	2 "
Newport News, Va.	May 25-30	9 "
Norfolk, Va.	May 25-30	7 " 1 death.
Portsmouth, Va.	May 25-30	7 "
Seattle, Wash.	May 30	1 case.
Spokane, Wash.	May 20	4 cases.

Small pox.—Foreign.

Sierra Leone, Africa.	Apr. 22-29	40 cases.
Prague, Austria.	May 6-13	2 " 1 death.
Bahia, Brazil.	Apr. 15-30	3 "
Rio de Janeiro, Brazil.	Apr. 7-11	2 " 2 deaths.
Cairo, Egypt.	Apr. 22-29	9 cases.
London, England.	May 6-13	1 death.
Hreslau, Germany.	Apr. 26	Black small pox reported from consular district.
Athens, Greece.	May 6-13	24 cases, 8 deaths.
Calcutta, India.	Apr. 15-22	2 "
Madras, India.	Apr. 22-29	1 death.
Tamsui, Formosa, Japan.	Mar. 11-31	19 "
Naga-aki, Japan.	Apr. 21-30	2 deaths.
Mexico, Mexico.	May 14-21	16 " 8 "
Nuevo Laredo, Mexico.	May 13-20	1 death.
Moscow, Russia.	Apr. 29-May 6	6 "
Odesa, Russia.	May 6-13	3 deaths.
St. Petersburg, Russia.	Apr. 29-May 13	22 " 5 "
Warsaw, Russia.	Apr. 29-May 6	1 death.
Constantinople, Turkey.	May 1-8	2 deaths.
Montevideo, Uruguay.	Apr. 1-8	2 "

Yellow Fever.

Bahia, Brazil.	Apr. 15-30	115 cases, 53 deaths.
Rio de Janeiro, Brazil.	Apr. 7-14	39 " 26 "
Cartagena, Colombia.	May 6-13	1 case, 1 death.
Vera Cruz, Mexico.	May 1-25	151 cases, 104 deaths.

Cholera.

Calcutta, India.	Apr. 15-22	16 deaths.
Yokohama, Japan.	Apr. 14-21	1 case, 1 death.

Plague.

Calcutta, India.	Apr. 15-22	83 deaths.
Tainan, Formosa, Japan.	Apr. 24	24 cases, 18 "
Taiichu, Japan.	Apr. 25	6 "
Taiichu, Japan.	Apr. 25	2 "
Tamsui, Japan.	Mar. 11-Apr. 12	807 " 583 "
Straits Settlements, Penang.	May 27	Plague present.

The American Surgical Association.—At the annual meeting held in Chicago last week officers for the ensuing year were elected as follows: President, Dr. Robert F. Weir, of New York; vice-presidents, Dr. Charles B.

Nancrede, of Ann Arbor, Michigan, and Dr. E. M. Souchon, of New Orleans; secretary, Dr. Herbert L. Burrell, of Boston; recording secretary, Dr. De Forest Willard, of Philadelphia; treasurer, Dr. George R. Fowler, of New York (borough of Brooklyn).

The Buffalo Academy of Medicine.—At the last regular meeting of the Surgical Section, on Tuesday evening, the 6th inst., a paper on Cystitis was presented by Dr. J. Henry Dowd and was discussed by Dr. D. W. Harrington, Dr. W. H. Heath, Dr. John Parmenter, and others. The annual election of officers followed.

Tetanoid Seizures.—Dr. Pierce Clark (*American Journal of Insanity*, April), as the result of a careful study of "tetanoid seizures," says:

"1. The exclusive tonic convulsions of *petit-mal* epileptic fits are not identical with tetanoid seizures. 2. Tetanoid seizures are clinical facts, although very rare; but a distinct classification of epilepsy, the so-called 'tetanoid epilepsy' of Prichard, is not proved. 3. Tetanoid seizures are but a modification of true epilepsy and probably have no relationship to tetanus."

Change of Address.—Dr. Simon Tannenbaum, to No. 9 Clinton Street, New York.

Army Intelligence.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 20 to May 27, 1899:*

PURVIANCE, WILLIAM E., Captain and Assistant Surgeon, will proceed to San Francisco to accompany RAY, P. HENRY, Major, Eighth Infantry, to his station in Alaska.

SHAKESPEARE, EDWARD O., Major and Brigade Surgeon, member of the board of medical officers on the emergency ration, appointed August 18th, is assigned to duty in Washington for an additional period of two months, for the purpose of completing his report.

VAUGHAN, VICTOR C., Major and Division Surgeon, member of the board of medical officers on the emergency ration, appointed August 18th, is assigned to duty in Washington for an additional period of two months, for the purpose of completing his report.

WILSON, WILLIAM H., Captain and Assistant Surgeon, is relieved at the Josiah Simpson General Hospital, Fort Monroe, Virginia, and will proceed to San Francisco for assignment to duty.

Society Meetings for the Coming Week:

MONDAY, June 12th: New York Medico-historical Society (private); New York Ophthalmological Society (private); Gynaecological Society of Boston; Burlington, Vermont, Medical and Surgical Club.

TUESDAY, June 13th: Buffalo Academy of Medicine (Section in Medicine); Rome, New York, Medical Society; Medical Society of the County of Rensselaer, New York; Trenton, New Jersey, Medical Association.

WEDNESDAY, June 14th: New York Pathological Society; American Microscopical Society of the City of New York; Society for Medical Progress, New York; Philadelphia County Medical Society.

THURSDAY, June 15th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement.

FRIDAY, June 16th: Baltimore Clinical Society; Chicago Gynaecological Society.

Letters to the Editor.

THE PERIOD OF INCUBATION OF MEASLES.

FRANKFORT, N. Y., June 2, 1899.

To the Editor of the New York Medical Journal:

SIR: In a letter to the *Journal*, May 8th, I called attention to a letter upon this subject from Sara Newcomb Merriek, M. D., published on May 6th, and I then expressed the opinion that the doctor's conclusions were based upon error. Notwithstanding the explanation in a letter of May 27th as to the medium of infection, and the correction of my inference as to the "little sister," I am still of the opinion that the doctor's conclusions, which are based upon this "experiment," are of no scientific value, because possible sources of error have not been properly eliminated. "The period of incubation of measles" is probably as well known as it ever will be. Competent observers are quite well agreed. The London Clinical Society, after painstaking observation and investigation, has placed the "period" at from seven to eighteen days, and oftenest at fourteen days. That means to the first symptoms, or about eighteen days to the beginning of the eruptive stage, which designates the time that we are sure our case is one of measles. In several cases of mild measles recently observed with reference to Koplik's symptom, I often found it absent. There are several important omissions in this report which I will indicate: The length of time that the little sister was sick; whether she had been kept from contact with others; the source of her infection; the existence of the disease in the community to any extent other than this one case; the presence of any suspicious sickness among the sixteen irregular attendants of the school; the attendance of the school children at other places of meeting—church, Sunday school, or parties; the presence in the school at any time prior to this supposed exposure of a "walking case," one in the stage of invasion, or one of the irregular form, which might later on be one of the "immunes." Again, of the cases which left school eight days after exposure we should know more. If the eight days means to the eruptive stage, which is the earliest that we can positively make a diagnosis, the period of incubation would be much less. If it means the beginning of first symptoms, the parents were remarkably well informed and prudent people. With all due respect to Dr. Merriek's ability as an observer, I can come to no other conclusion than that some child infected the school prior to the supposed exposure or "experiment." I agree in the main to the doctor's conclusions, however, based upon the known characteristics, of the disease, rather than the so-called experiment. Infection has undoubtedly been carried on the clothing, but is never carried to the extent that the laity presume. It is very contagious in the early stages, as I have repeatedly observed. In conclusion, I wish to protest against experiments of the kind reported, though I believe this one to have been harmless. It is a serious mistake to expose children to measles, as I have known mothers to do, "to have it over with." It is better never to have it. It is a dangerous belief for a physician to hold that it is a trivial disease. That adults have the disease harder than children can not be proved to be true. Large experience and good diagnostic ability will prove beyond question that even mild cases have a certain amount of fatal complications, and that serious chronic

diseases result much more frequently than was formerly supposed. Physicians should not experiment deliberately along this line, for it is more than dangerous.

GEORGE M. MCCOMBS, M. D.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XXII.

RECOVERY OF COMPENSATION.

(Continued from page 792.)

Proof of Claims against Counties, etc.—The manner of proving claims against counties and towns for services rendered to paupers and in performing post-mortem examination and the like differs so materially in the several States, the method being nearly always arranged for by the statutes of the particular States, that it will be unwise to devote the space necessary to a treatment of the subject that would be valuable to residents of all States. The method of proving the value of such services is, however, pretty much the same in all States; we will therefore make an extended examination of the case of Board of Commissioners of Marion County *vs.* Chambers, in which considerable light is thrown upon the subject. In this case Dr. C. was employed by the coroner to conduct a post-mortem examination, for which he filed a claim of \$180. The commissioners allowed him \$105, and from that order he appealed to the superior court, where a verdict was given him for the full amount of his claim. The case was then appealed to the supreme court, which reviewed the trial of the case in the superior court and affirmed the judgment of that court. There being much evidence fully sustaining the value of the doctor's services as charged and allowed, the court confined itself to an examination of alleged errors of the superior court in admitting and rejecting certain evidence.

The counsel for the board of commissioners asked the doctor, "What has been the average daily income from your profession for the two years past?" The doctor's counsel objected to the question, and the court sustained the objection. The supreme court, in passing upon this ruling, said: "Whether the income of the appellee (the physician) was much or little was entirely immaterial. If a surgeon properly performs a surgical operation he is entitled to recover the reasonable value of his services, neither more nor less, whether his professional income be ten or ten thousand dollars a year. The value of the services can not be measured by the professional income of any series of years. If the physician or surgeon possesses the requisite skill and knowledge, and exercises such knowledge and skill properly, he is entitled to be paid the reasonable value of services rendered by him, irrespective of the question of his yearly professional income." The plaintiff produced two physicians and surgeons to testify in his behalf as to the value of the services performed; these witnesses testified upon their examination in chief that they were physicians and surgeons, and that they were competent to testify to the value of services rendered in making post-mortem examination; but, on cross-exami-

nation, one of them said: "I don't know what physicians have charged for making post-mortems for the county; I know nothing of the prices at which services can be procured; I judge from what I think it would be worth." The other witness said upon cross-examination: "I have never made examinations for the county; my testimony is based upon all the circumstances. I base my opinion on what I think is the value of such services, irrespective of the price charged or paid." The counsel for the board of commissioners then asked to have the testimony of these witnesses stricken out, which the trial court refused to do. The supreme court said: "No error was committed in overruling appellant's motion. The testimony was competent, for the witnesses were shown to be experts, and to possess such knowledge, skill, and acquaintance with the subject under investigation as entitled them to express their opinions to the jury. They may have had some knowledge of the value of such services, without knowing anything at all about what others were charging for like services. . . . It is clear, from the statements of the witnesses, that they were skilled in their professions, and that they did have sufficient acquaintance with the nature and value of services rendered in post-mortem examinations to entitle their opinion to go in evidence." The board of commissioners' counsel put the question to one of the members of the board: "At what price could you have procured competent physicians to make post-mortem examinations during the years 1877 and 1878?" The physician's counsel objected to the question, and his objection was sustained. Upon the correctness of this ruling the supreme court said: "The question in issue was, not what others would have done the work for, but what was the reasonable value of the services of appellee (the physician). It was no more competent for the appellant (the board) to introduce the offered evidence than it would have been for the appellee to prove that any other surgeon would have charged twice as much as the sum claimed by the appellee. It was competent for appellant to call competent witnesses to give their opinions of the value of the services, but not to prove particular bargains or offers."*

In States where the statutes authorize the board having charge of the particular matter to limit the amount of relief to be furnished, such board may, before the relief is furnished or services rendered, establish a limit, but where no such limit has been established, the board must allow the reasonable value of the services rendered.†

In passing from the subject of presenting and proving claims against towns, counties, etc., it is relevant to say that a doctor who has rendered services to a poor person, and has presented his bill for the same to the proper officer of the municipality, is barred by the auditing and allowing of such bill from ever collecting the same from the patient, and it makes no difference whether the bill is allowed at its face or at a reduced valuation‡.

Defense. The physician having shown his employment, established the fact that the services were rendered, and proved the value of those services, it then becomes incumbent upon the patient to show some just

reason why he should not pay, and, if he fails in this, judgment will be rendered against him. Experience has shown that the human mind is very fruitful in devising excuses and discovering reasons for avoiding obligations; it therefore usually happens that the defendant has a defense. Perhaps the most common defense, when the suit is between the physician and patient, is that of general denial, which simply necessitates the strict proof that the services were rendered as alleged, and that they are of the value claimed. Frequently the defendant produces witnesses, who, it has been heretofore shown, must be physicians, to prove that the services are of a less value than that claimed. In such a case the plaintiff should be careful to secure as his witnesses men of good professional standing whose judgment is esteemed and integrity undoubted. The defense has been interposed that, excepting for those visits specially requested, the patient is not liable unless the physician shows some reasonable necessity for the additional visits. This defense has no legal weight; a physician, being employed to attend a patient, is the proper and the best judge of the number and frequency of visits necessary, and, in the absence of proof to the contrary, the court will presume that all professional visits made were deemed necessary and were properly made. Justice Temple, of the supreme court of California, said: "It would be a dangerous doctrine for the sick to require a physician to be able to prove the necessity of each visit before he can recover for his services. This is necessarily a matter of judgment, and one concerning which no one, save the attendant physician, can decide. It depends not only upon the condition of the patient, but, in some degree, upon the course of treatment adopted."*

In the case of *Jeffries vs. Harris* the defendant attempted to show the character of the physician, but was not permitted to do so. The court said: "Character was not put in issue by the nature of this action, and the defendant is equally liable on his assumption, whether the plaintiff's character were good or bad; for, if he chose to employ him as a physician, it is not competent to him, afterward, to say that he is not a good one, and, therefore, that he will not pay him. If, indeed, the plaintiff had imposed on the defendant by false pretensions to skill, he would have been responsible for any injury done him; but, in this case, the plaintiff is entitled to compensation for skill and labor, whatever they may be."‡

A very common sort of defense is that in which the defendant admits the rendering of the services but claims that they were so unskillfully rendered as to be injurious; and frequently he files a counter-claim for damages resulting from such unskillful or negligent treatment. The constant recurrence of cases in which this sort of defense is interposed will justify a careful examination of the law governing the proof. Many of the trial courts seem to have been of the opinion that when a patient pleaded as a defense to a physician's suit to recover compensation for professional services that such services were not rendered with skill, this plea immediately cast the burden upon the physician of showing by a fair preponderance of evidence that the services rendered by him were performed with all necessary or required skill. The courts of last resort have, however, universally declared this to be a mistaken view, they holding the law to be that where the physician has made

† *Hunter vs. Jasper Co.*, 40 Ky., 569.

‡ *Wood vs. Wilson*, 70 Hun., 168; 24 N. Y. Supp., 287. See *N. Y. Medical Journal*, May 13th, p. 692.

* *Endre vs. Meares*, 40 Cal., 37.

‡ *Jeffries vs. Harris*, 1 Hawk (N. C.), 195.

a *prima-facie* case by proving his professional character, his employment by the defendants, the rendition of the services and their value, he is entitled to judgment unless the defendant can show by competent evidence that he has been guilty of negligence or want of proper skill in treating the particular patient.* Nor will the fact that a patient grew worse under the plaintiff's treatment and grew better after he was discharged show that the physician was guilty of negligence or unskillfulness in treating him. To illustrate more fully and show the character of evidence required, a quotation is taken from a case in point: The patient in this case had sustained a serious injury by the explosion of a dynamite cartridge and the plaintiff had been called as a specialist to treat his eyes and ears. The defense interposed was that of improper treatment. In commenting upon the evidence offered to establish this defense the court said: "It is claimed that the plaintiff improperly applied and used a tube of hot water over the nose to cure the ailment or injury to his eyes; that the heat was so great as to be injurious. Other physicians were in attendance on the patient, but their evidence was not produced. No surgical or medical witness was called by the defendant to say that the treatment was improper or negligent in the least degree, whatever uneducated persons or non-experts might conjecture on the subject. The plaintiff could not be convicted of malpractice on such evidence. He could not be held responsible simply because he failed to cure the defendant's son, nor for mere misjudgment in treating him, if the treatment was such as a physician and surgeon of ordinary knowledge and skill would apply."†

Nor is it a valid defense to a suit by a physician to recover the value of his services to show that the nurses in the hospital to which the patient went upon the physician's advice were negligent or careless, it not being shown that the physician was proprietor or manager of the hospital.‡

Drunkness is also sometimes pleaded as a defense to such an action. If a physician who is called to attend a patient is in such an intoxicated condition as to be unable to fulfill the duties of his profession, this is not only a complete defense to an action commenced to recover compensation for those particular services, but there is, under the law of some States, a criminal liability involved. If, however, a patient, after the doctor has treated him in an intoxicated condition, continues to send for or employ him, he will be held to have waived all objection to his habits of intoxication and will not be permitted to plead such a defense."

Effect of Judgment for Recovery of Fee.—A judgment being entered in favor of the physician in a suit commenced by him to recover the value of his professional services, it is interesting and valuable as well to inquire what effect such a judgment will have upon a possible right of action against him and in favor of the patient growing out of unskillfulness in the performance of the same services for which he has just recovered. It is a general principle of law that a judgment of a court of concurrent jurisdiction directly upon a point is a bar to an action upon the same point and between the same parties in another suit.

The appellate court of New York has applied this doctrine to its full extent. In this instance suit had been commenced by a patient to recover damages, laying the amount at five thousand dollars, from his physician for unskillful and negligent treatment of a dislocated elbow and fractured arm. The physician then commenced an action before a justice of the peace to recover the value of his services in the treatment complained of from the patient, who was plaintiff in the malpractice suit. The patient appeared in the suit instituted before the justice of the peace for the recovery of fees, but interposed no defense, and judgment was entered against him to the amount of six dollars and fifty-eight cents. The physician, then, as a defense to the patient's action for damages from malpractice, set up the judgment rendered by the justice of the peace. Upon the principle above given the supreme court, and afterward the court of appeals, held that the judgment of the justice was a complete bar to the action for damages.* The courts of West Virginia have declared themselves in harmony with this decision;† so also have those of New Jersey‡ and Arkansas.§ The contrary view has, however, been taken by the courts of Indiana,|| Ohio,¶ and Wisconsin.⦿

Pith of Current Literature.

Cocainized Chloride of Ethyl for Local Anæsthesia.

—M. G. Milian (*Revue médicale*, May 24th) speaks highly of hydrochloride of cocaine in one-, two-, three-, four-, or five-per-cent. solution in chloride of ethyl in tubes similar to those widely used for the ethyl alone. Eucaine could also be used in the same way, but did not appear to be so efficient as cocaine. In this method the chloride of ethyl is not used for refrigerating purposes, but simply as the vehicle of the cocaine, removing the fats from the skin, penetrating the superficial cellular layers thereof, and depositing the cocaine in their interstices. The advantages claimed for this proceeding are the obviating of hypodermic injection and the lessened liability to cocaine intoxication. Moreover, it can be used with the thermal cautery, since the operation is not begun till after all the ethyl chloride is evaporated. The application may take place either by a pledget of cotton saturated with the medicament, specially serviceable when the part to be anæsthetized is deep-seated or inaccessible, or it is desired to avoid affecting contiguous parts; or by atomization. Anæsthesia is obtained in about five or six minutes.

Examination of the Spleen.—James Cantlie, F. R. C. S. (*Clinical Journal*, March 1st; *Medical and Surgical Review of Reviews*, April), says that in the usual position, with the patient lying on the back, by palpation and percussion it is easy to find the spleen when greatly enlarged; but when of normal size, or even moderately big, it is impossible to determine, even ap-

proximately, its exact position or size. The spleen is regarded as presenting relations with the anterior aspect of the abdomen, but this is a fallacy. It is situated far back in the hollow of the ribs, being accommodated in the angles of the ninth, tenth, and eleventh. The long axis runs parallel with the tenth—"the splenic rib"—and the inner (upper) end of the organ reaches to the head of the rib. The outer (lower) end of the spleen comes no farther forward than the posterior axillary line, so that to attempt to percuss out the spleen from the front with the patient supine is, in the case of the normal spleen, an absurdity. With the patient in the horizontal position and rolled over on the right side, fallacious signs will also result as the organ moves forward with the altered position of the body. Again, with the patient prone it is impossible to percuss out the spleen from the back, as it leaves its position (unless adherent from old perisplenitis) and rolls forward to the anterior part of the abdomen. It is therefore only when the body is in the erect position that the spleen can be percussed out properly, for the organ is only then maintained in its normal position. The spleen does not descend when the erect or sitting position is assumed.

Tuberculosis of the Symphysis Pubis.—M. von Bünchner (*Annales de chirurgie et d'orthopédie*, April) has reported a case of tuberculosis of the symphysis pubis in a woman of fifty-seven who was cured by operation. M. Bünchner says that the few recorded cases present a uniform clinical picture. The affection begins with inguinal pains of neuralgic character; then, after a lapse of time, an abscess forms in the hypogastrium behind the abdominal muscles. This abscess leads to the formation of fistule, sometimes in the pubic, sometimes in the perineal region. The swelling resulting from this abscess has been confounded with hernia or lipoma. Prognosis is favorable not only as regards cure, but also from a functional point of view.

Xeroform in Corneal Ulcer.—Marcinowski (*Therapeutische Monatshfte*, xii, 38; *Canada Lancet*, May) finds that xeroform is much preferable to iodoform in the treatment of corneal ulcer. Having succeeded with xeroform in a case which had previously given bad results with iodoform, he has since relied solely upon the former, with uniformly good results, both in ulcerations and in dressings for corneal injuries. Wounds heal quickly under its influence without leaving a scar.

The Relation of the Nervous System to Albuminuria.—Dr. J. H. Brownlow (*Albany Medical Annals*, May), in concluding an interesting paper, says that overstimulation, irritation, or lesion to portions of the floor of the fourth ventricle of the brain, or the fibres passing from its immediate vicinity, at once affect the circulation of the kidneys; and if persistent and severe, are quickly followed by all the pathogenic evidences of acute albuminuria. In the initial stage, particularly in the chronic form, our attention should be early directed to the nervous system, if we hope to arrest its development. Indispensable to success in the treatment of the disease is a correct knowledge of its etiology and pathology. The prodromata of parenchymatous and interstitial nephritis evidence themselves in a most direct and positive manner in disturbances and derangements of the whole nervous system. At every stage, from the initial to the final, the varied series of nervous manifestations, renal and arterial pathological conditions, if

properly interpreted, clearly and unmistakably point, in the author's opinion, to a nervous origin. In conclusion, he draws the following inferences:

That all the alleged causes of acute albuminuria, with the exception of the toxins of scarlet fever and diphtheria, are devoid of specific pathogenic power and should not be accepted.

That the opinion of leading authorities that these toxins primarily act on the tissue elements of the kidneys, causing inflammation of these organs and resulting in acute or chronic albuminuria, is unwarranted, and is controverted by anatomical and physiological principles.

That in the highly organized and susceptible nervous system, with its primary, perpetual, and controlling dominion over metabolism, is to be found the primary morbid process from which all the other grosser lesions are the direct result.

That, as in acute albuminuria the true aetiological factors are the *toxines* of scarlet fever and diphtheria, so in the chronic form *auto-toxines* are the active pathogenic factors, and their specific action is primarily evidenced on the nervous system.

That severe mental strain, intense worry, deep and profound sorrow, the silent grief of domestic and financial misfortune, are the most active predisposing causes in albuminuria.

That the obscure and constant nervous manifestations are more reasonably accounted for on this theory than upon any other.

That the pathological conditions found in the renal organs, arterial system, brain, spinal cord, and sympathetic ganglia are local manifestations of a deranged and diseased nervous system, developed by auto-intoxication and resulting in deranged metabolism.

To Control Epistaxis.—Dr. Boyd Cornick (*Canada Lancet*, May) says that all that he has found necessary has been to fashion with a pair of scissors a dry plug of prepared sponge, in size and length comparable with the little finger of a twelve-year-old boy. This should be carefully soaked in boiled water to free it of grit, squeezed dry to free it of unnecessary fluid, and inserted its full length, gently, along the floor of the bleeding nostril. No styptic is necessary; it would be needlessly irritant. The expansive pressure of the soft sponge against the bleeding site, increased by the coagulation of a few drops of blood in its interstices, will check the bleeding at once. It should be removed in twelve hours, and under no circumstances should it remain longer than twenty-four. Melted vasoline containing 0.5 per cent. of carbolic acid, applied with a medicine dropper in liberal quantities, is the only local treatment called for afterward.

Aphasia from an Unusual Cause. Dr. A. Ferree Witmer (*Philadelphia Polylinic*, supplemental number, January), in a communication recently presented to the Philadelphia County Medical Society, remarked that from certain facts previously enumerated there grew up the conception of the zone of language comprising (1) Broca's convolution, lesion of which caused inability to remember movements necessary for articulation; (2) the superior temporal convolution, lesion of which caused inability to understand spoken words; and (3) the angular convolution, lesion of which caused inability to interpret words that could be seen. These three collections of cells, or centres, were connected by fibres

known as association tracts. It would be seen, therefore, that the subject of aphasia could be conveniently studied under five headings:

1. True aphasia. 2. Motor aphasia. 3. Sensory aphasia. 4. Associative aphasia. 5. That due to combined conditions. True or intellectual aphasia would follow upon a lesion in any one of the three areas already outlined. It had been proposed to call this form aphasia of apperception. By this term was meant the combination of central excitation with any incoming sensory stimulation before that stimulation aroused such excitation in the cerebral cortex as to bring into consciousness a complete perception. A more descriptive term for lesion in any of these three brain areas would, in the writer's opinion, be central aphasia.

This central form of aphasia held a median position between the cephalad fibres, known as sensory tracts, and those caudad, known as motor tracts.

When all three of these brain areas were involved the condition was called complete aphasia. Associative aphasia resulted from the disturbance of connection between the parts comprising the central structures.

Combined aphasia was, as its name suggested, a combination of two or more of the above forms in one individual.

The author then presented a patient on whom he remarked as follows:

"You will notice that he correctly interprets the sounds that he hears, that he reads understandingly, and that muscle movements, although stilly, are correctly performed. We can, therefore, exclude the superior temporal, the angular, and Broca's convolutions from participation in the lesions. Dependent upon the association tract involved, different terms are employed to express the disturbed function; thus, when the tract between the auditory area and Broca's convolution is disorganized, the condition is spoken of as paraphasia, etc. As the patient readily and correctly coordinates the different centres forming the zone of language, we can exclude a lesion of the association tracts. You will, I think, agree that the patient attempts to speak when directed—i. e., the sensory tract is intact.

"But you have also noticed that his attempts to speak are frequently abortive. It would seem, therefore, that we are dealing with a condition known properly as motor aphasia. The history of this patient until his eighth year was uneventful; from that time, however, without apparent cause, he was seized with convulsions of the *grand-mal* type, which recurred at monthly intervals until last January, when he went into the status epilepticus and remained unconscious for three hours. On the following day the entire right side was found to be paralyzed and speech lost. Improvement since then has been slow but continuous, the face, trunk, leg, arm, and speech improving in the order named. The site of the lesion is doubtless in that part of the brain most frequently involved in cerebral hemorrhage, the knee and posterior limb of the internal capsule. Since January the boy has had but one convulsion, the movements in which were generalized. Examination of the heart is negative; there is no history of luetic infection; knee, elbow, and wrist jerks in the right accentuated. Inquiry into the family history on the maternal side gives a line of goitrous ancestors, the mother and grandmother of the patient being afflicted with this affection. On the paternal side we find a grandfather who became insane at about the middle of life. It is highly probable, therefore, that the boy has inherited an unstable

nervous system, which at the time of puberty and under the additional stress of a series of convulsive seizures gave way."

Nitroglycerin in Hæmoptysis.—Flick (*Centralblatt für innere Medizin*, 1898, No. 27; *Annali di farmacoterapia e clinica*, January and February, 1899) has treated very successfully three cases of hæmoptysis that were resistant to all ordinary measures with very small doses of nitroglycerin.

Gangrene of Lung Treated by Creosote Vapor.—Dr. W. Devereux (*British Medical Journal*, March 4th) reports the case of a boy, aged eleven years, admitted to the Tewkesbury Hospital with signs of consolidation of the left lung throughout the axillary region, accompanied by hectic, perspiration, and other clinical symptoms of phthisis. On June 13th there was a sudden change in the quantity and character of the expectoration. It increased to half a pint in the twenty-four hours. It was watery and opaque, with a greenish tinge, slightly streaked with blood, and lumpy. It did not coagulate on boiling. On microscopical examination an abundance of pus cells was found, but no lung tissue or tubercle bacilli. The smell, especially during an attack of coughing, was horribly fetid. On auscultation over the dull area, physical signs of a large cavity were found.

It was determined on June 20th to try the inhalation of coal-tar creosote vapor. A small room, connected with the hospital by a porch, was used, the fireplace and window being rendered as air-tight as possible, and the creosote vaporized in a metal dish over a spirit lamp. The patient was provided with plugs for the nose and watch glasses for the eyes. The vapor at first aggravated the coughing, and the patient brought up a large quantity of watery sputum, but after ten minutes the cough diminished, and he felt much easier. At the end of twenty minutes the boy felt weaker, and was taken back to bed, when he again expectorated a large quantity of sputum.

During the next week the inhalations were continued, each lasting from ten to fifteen minutes. His general condition showed considerable improvement, the factor of the breath ceased, and the cavity in the left lung showed signs of diminishing.

On June 28th the patient went out of doors. By July 4th he had gained three pounds and a half in weight. The inhalations were continued daily till July 30th.

The patient was discharged on August 3d, the dullness having greatly diminished. He was seen again on his return from the convalescent home on August 17th, when he looked extremely well; he had gained fourteen pounds and a half, and the physical signs in the lung had completely disappeared.

The Treatment of Exophthalmic Goitre with Sulphate of Quinine.—The *Therapist* for May 15th, citing the *Journal de médecine interne* for December 15, 1898, says that Paulsøe agrees with Reynier that exophthalmic goitre is not, properly speaking, a disease of the thyroid gland, but a disease of the blood-vessel system, a vasodilatation, causing cerebral congestion, with an increased activity of the thyroid gland, and other reflex symptoms. In the treatment of this trouble a vasoconstrictor is called for, and one meeting the requirements better than all others is sulphate of quinine. He reports three cases, one in detail; all were greatly benefited by the treatment.

Proceedings of Societies.

BROOKLYN MEDICAL SOCIETY.

Meeting of March 17, 1899.

The President, Dr. JACOB FURS, in the Chair.

The Voice in Diagnosis.—This was the title of a paper read by Dr. ALEXANDER J. C. SKENE. (See page 809.)

Dr. JOSEPH MEYER said it was not often that one had the pleasure of hearing so interesting a paper as that read by Dr. Skene.

He had left very little room indeed for discussion—in fact, so thoroughly exhausted was the subject that, to those who had not had the opportunities to read and learn these things as completely as the doctor had done, especially with regard to the emotional, psychical, and psychopathological characteristics of the human voice, the paper's importance was apparent.

The speaker cited the histories of a few cases which were interesting on account of their rarity. First he alluded to the condition of apathy referred to as a prognostic sign. In peritonitis following operation, and in diseases of the pelvic organs, he always regarded the condition of apathy as a bad sign.

He cited the case of a young lad who had lost his voice during an attack of whooping-cough. A complete examination of his larynx had revealed no visible cause. The defect had been due to a central lesion, and he had improved under treatment.

Another was a case of bradylalia in a man thirty-two years old, in whom the defective speech had been the means of making an early diagnosis of paresis, of which the man had died two years later.

Still another case was one of aphonia and dyspnea due to a calcified lymphatic gland near the bifurcation of the trachea, which had caused a perforating ulcer of the trachea. Laryngeal examination had been almost impossible on account of the inability of the patient to remain in an upright position. The patient had been removed to a hospital in a suffocating condition, and tracheotomy had been performed by the house surgeon. The breathing had improved slightly, but the patient had died the next day. At the post-mortem, a hole about a quarter of an inch in width had been found in the trachea. The wall had been very much thickened about it. The air had passed into the mediastinum and cellular tissue of the neck and chest. There had been no sign of abscess. There was no reference to such cases that he could remember, except a few described by von Ziemssen.

In a case referred to the speaker by Dr. Beasley, that of a boy aged seventeen years, he had found a defect in the voice which had been traced directly to a congenital bony occlusion of the posterior nares. There had been also in this case an absence of the entrance of the Eustachian tubes and absence or loss of both drum membranes. His hearing had been W. R. 1'; L. 5'. It had been almost impossible to understand the patient's speech. After a passage had been opened in the posterior end of the septum and also into the vault his speech had become normal after practice.

Dr. Meyer thought that many defects in speech in the young were due to bad or careless teaching. The facts which had lasted for years were sometime corrected in a short while. While reading a paper on speech defects, Dr. H. Riedel, who was quite a linguist, alleged that he could pronounce the letter *r* only as a gut

tural; in a short time the speaker had taught him to pronounce it as a linguopalatal.

Then, again, there were conditions due to paralysis of the soft palate following diphtheria, and ulceration and destruction of the palate altered the voice materially. There was also quite a marked change in the voice when adenoids were present.

Dr. A. C. BRUSH said that every one received two educations in this world—one which was taught to him, and the other which he taught himself. The latter was by far the more valuable. Dr. Skene's paper belonged to this class, and treated of a subject which had not received the attention it deserved. As he had said, the voice might present well-marked changes in the various forms of insanity. In mania, for example, it was rapid and continuous, the subject being frequently changed in the middle of a sentence, with failure to answer questions, incoherency, and irrelevant ejaculations. It was, as a rule, loud and high-pitched, and corresponded to the characters which the doctor had described as those of sorrow. This change in the voice was often of value in distinguishing between melancholia and the depressed form of paranoia, especially before the delusions of persecution had taken definite shape. The paranoiac talked naturally and his voice would correspond to the amount of joy or anger or depression which, at the time, dominated his field of consciousness. In general paresis the voice changes were often among the first, and frequently preceded the other signs, and, therefore, were of great value. The close resemblance between the early stages of paresis and neurasthenia were well known, but they presented this difference in speech: Patients in both groups were apt to talk rapidly and leave out and misplace words, but the neurasthenic recognized his mistakes and corrected them, the parietic did not. The tremor of the lips and tongue, when present, added an indistinctness to the parietic's speech which was very characteristic. In hysteria we often found voice changes of a paralytic or emotional character. The most frequent in the speaker's experience was a complete aphonia and a high-pitched nasal voice. In the organic affections we also found some well-marked changes. In multiple sclerosis the patients frequently spoke in a slow, monotonous manner, making a distinct separation between syllables, and, from the tremor of the lips or tongue, the speech was thick. In bulbar paralysis the earliest signs were often those due to loss of power in the lips and tongue, and consequently there was an inability to pronounce the letters *p*, *m*, *b*, *s*, and *t* properly. In cerebral hemorrhage, thrombosis, and embolism, the voice frequently presented the changes due to the various forms of aphasia or paralytic conditions of the larynx. The speaker felt that he could only touch upon the surface of such a vast subject, as Dr. Skene had so ably laid it before them, and he was glad to have had the privilege of hearing a paper which was certainly one of the most valuable contributions to modern medicine.

Dr. PETER SCOTT stated that Dr. Skene's remarks about partial aphonia reminded him of a case that he thought worth while mentioning. It was one of hysterical aphonia in a young woman who had been brought from the west coast of Scotland to the east coast, where he had been in practice at that time. The east coast of Scotland was more bracing and clear than the west, which was so often enveloped in rain-fogs. The patient had not been long under his care before one or two things were noticed: First, that she would sing in church in a high-pitched voice; second, that, being very fond

of babies and children, she would sit and sing or "croon" to the baby, also in a high-pitched voice; and that when she laughed, vocal sounds were produced. Otherwise all conversation was carried on in a whisper, and that with apparent effort. Making use of these facts, the speaker had taken her to the piano, and had struck a note quite above the ordinary conversational pitch, and had kept her reading at that pitch, all the time striking the note on the piano. Then, coming down half a tone, a few other lines were read at that pitch, and so on. With that kind of vocal gymnastics the speaker had expected to bring her down to being able to read at a pitch suitable for ordinary conversation. During the first week he had found that the voice broke at a certain note on the scale; he could not state just exactly what note it was, but remembered that it was near the point where musicians said the middle register changed into the upper register. He had thought it strange at the time that that part of the vocal apparatus which was most used, and was usually the strongest, should have suffered from loss of nerve power, while the part used to produce tones in the upper register, which was not usually the strongest part of the voice, should have retained its power.

Two or three weeks of this vocal gymnastics had brought the voice back to the middle register. Of course, other treatment had been helping the voice also.

Dr. JAMES J. BOWEN thought it a happy privilege to listen to a paper which, he said, was one of the kind that served as milestones in the progress of medicine. Dr. Skene had thrown open the doors of an unexplored field, and, with an elegance and modesty characterizing him thoroughly, had told of his personal observations in this line during his long and busy career.

Papers of this character had always been the signal-bell for deep investigation. Coming as it did from such an eminent source, he felt sure that when Dr. Skene's paper was copied and translated into other languages, and presented to the men of medicine throughout the world, the result to scientists would be as gratifying as the result of Czerniak's paper on adenoids had been some years ago. Then the medical world had been rife with expectation as to what discoveries might have been made in the then new field, and the eagerness and alacrity with which the subject had been cleared up was, Dr. Bowen said, a standing tribute to the medical profession. He hoped that the subject that had been brought before them so eloquently would soon be divested of its mysteries; that diagnosticians might have a clear, unclouded conception of what these voice changes meant.

To none in the medical profession was this subject of more interest and value than to those who were interested in the nose and throat. Its value to the neurologist, the surgeon, and the general practitioner had been well explained. To one who was at all observant these voice changes were pathognomonic in many affections. The tone and pitch of the voice were considerably altered in nasal obstruction from hypertrophied turbinate bones, polypi, deviated septa, or any abnormality. In adenoids the character of the voice told its own story. In laryngeal affections the hoarse, harsh quality of the voice told of a constitutional disease. Where there was an absence of the soft or hard palate, due to disease or other cause, the voice was peculiar in its resonance, enough so to enable the physician to tell without examination just what the condition was. And so with many other affections of the nose and throat which had a peculiar deflection of the voice which, when once heard,

was ever after easily recognized. When we found a patient with a voice that appeared to be high-pitched, dead, or muffled, overresonant or hoarse, the nose, throat, and larynx should be examined, and, if no primary cause was found, there would be found at least something that would guide the physician to a correct diagnosis, maybe, before symptoms of greater importance or danger had manifested themselves. He had frequently identified patients in the clinics by some characteristic of their voice when, after an absence of a year or more, they returned for treatment.

Would the breaking of the voice ever be explained? he asked. Why was there a change of quality or something in the same note when sung in one register going up and in another coming down? Should we some day thoroughly understand the speaking voice, the singing voice, the voice crying, and the voice laughing?

The voice was music produced by the most delicate of musical contrivances, the larynx, differing only in its qualities from any other musical instrument; and, as we imparted different emotions or impressions by the varied uses of that voice, why could we not study the possibility of using other more common musical instruments for the same purpose, and thus commune with the mute, with the birds, and with all animals which were as susceptible as, if not more so than, we to musical vibrations? These questions, he hoped, would be answered when the investigation which Dr. Skene had the honor and good fortune to start was finished; then the world would thank the society for the paper, and in particular its able and eminent author Dr. Skene.

Dr. SKENE said that the discussion of his paper reminded him of his experience in consultation with his professional brethren in the past, in which he had always received more than he had given.

He felt conscious of his lack of knowledge regarding the voice changes in diseases of the voice-producing organs and of the brain and nervous system, and he thought that this deficiency had been met by the remarks of Dr. Meyer, Dr. Bowen, and Dr. Brush. Their contributions were certainly of the greatest possible value, and gave that completeness to the paper in this department which, he said, was very much needed. He had been deeply interested in the remarks of Dr. Brush upon the voice changes in mental depression and brain diseases. He had long been conscious that the voice was modified in these affections, but to what extent and in what direction he had had no opportunity of discovering.

The case related by Dr. Scott brought out, he thought, a portion of the subject which he had entirely overlooked in composing his paper—viz., the liability of the breaking of the voice in running from one register to another. This had been known to occur in some of the most talented and cultivated voices. One of our most celebrated singers suffered from this defect or accident, which would sometimes occur in spite of all her culture and great care to avoid it. He had never heard of a case so marked as the one related by Dr. Scott, and he was sure that we were on the right road to discover the cause of this breaking.

Dr. SKENE said that when selecting this subject for consideration he had been guided by a full assurance that, although there had not been much said of the subject in our literature, there was a great deal of valuable knowledge scattered among the medical profession, and he had hoped, in calling attention to this subject, to gather in from the members of the society some most valuable information, and he had not been disappointed.

Book Notices.

Vaccination: its Natural History and Pathology. Being the Milroy Lectures for 1898 delivered before the Royal College of Physicians of London. By S. MONCKTON COPEMAN, M. A., M. D. Cantab., M. R. C. P. Lond., Medical Inspector to her Majesty's Local Government Board, etc. London and New York: The Macmillan Company, 1899. Pp. x-257. [Price, \$2.]

A MORE able and excellent treatise than the work before us it would be difficult to imagine. The individuality of the subject and its distinctiveness both contribute to the result in the hands of such a writer as Dr. Copeman, and nobody will read his historical introduction without feeling that the subject has acquired a new interest.

From the historical the treatise passes to the pathology of vaccinia, and chapter ii takes up the relationship between that disease and small-pox. In the third chapter is most interestingly described the history of various lymph stocks, and in the fourth and fifth chapters respectively the histology and the bacteriology of vaccinia are treated of. A brief though interesting chapter (the seventh) deals with the antitoxic treatment of human variola, and concludes with an expression of doubt as to the future of the practice until cultivation outside the body is possible with the microbe of variola.

The concluding chapter is devoted to glycerinated lymph, and the subjects of the preparation and storage of vaccine are continued in an appendix. The work, as its title implies, is essentially non-clinical, but for the histology and pathology of vaccination we do not know its superior.

Practical Materia Medica for Nurses. With an Appendix containing Poisons and their Antidotes, with Poison Emergencies; Mineral Waters; Weights and Measures; Dose List; and a Glossary of the Terms used in Materia Medica and Therapeutics. By EMILY A. M. STONEY, Late Superintendent of the Training School for Nurses, Carney Hospital, South Boston, Massachusetts, etc. Philadelphia: W. B. Saunders, 1899. Pp. 5 to 306. [Price, \$1.50.]

THIS work is no more and no less than a much abridged materia medica, and we are at a loss to discover wherein lie its peculiar advantages "for nurses" as compared with a host of the smaller and well-known works upon the same subject. As we have many times said, we are not of those who esteem highly the teaching of a difficult subject by much condensation and epitomizing. As an example of the much-attenuated text-book, however, the volume under discussion is not ill prepared.

The first part of the book is introductory and concerns pharmacological classification; the second presents drugs, their sources, action and uses, and doses and toxicology, all much abbreviated. The third section treats of poisons, antidotes, emetics, mineral waters, weights and measures, doses, etc. As we have said already, the book is the equal of most of its kind.

Materia Medica and Therapeutics. An Introduction to the Rational Treatment of Disease. By J. McLELL BUECH, M. A. Aberd., M. D. Lond., Fellow of

the Royal College of Physicians of London, etc. Philadelphia: Lea Brothers & Co., 1899. Pp. xii-609. [Price, \$1.50.]

THIS work commands our high regard; indeed, we know of none we could more gladly commend to the student of medicine for the pointed and forcible and at the same time interesting presentation of a most difficult and none too agreeable subject. These qualities we have discovered by a very constant employment of the book. The present edition calls for no detailed consideration. It contains those recent additions to therapeutic equipment that have shown themselves worthy of more than temporary notice, and it conforms to the most recent edition of the *British Pharmacopœia*. To the American student this latter fact can be at most but a slight detriment, for many excellent dose books founded upon the *United States Pharmacopœia* are in the market whose use conjointly with the book before us will make an ideal combination.

Treatise on Human Physiology. For the Use of Students and Practitioners of Medicine. By HENRY C. CHAPMAN, M. D., Professor of Institutes of Medicine and Medical Jurisprudence in Jefferson Medical College, Philadelphia, etc. Second edition, Illustrated with Five Hundred and Ninety-five Engravings. Philadelphia: Lea Brothers & Co., 1899. Pp. 9 to 924. [Price, \$4.25.]

THE second edition of Dr. Chapman's work is constructed upon the plan of the first edition, but much revision marks the later issue, as physiological progress has required. In particular, the additions concerning physiological chemistry and the functions of the nervous system are to be noted, but apart from these features the work represents all that is most modern in the knowledge of human physiology and, what is more, the matter is more than commonly well presented.

The Philosophy of Memory and Other Essays. Consisting of Articles on the Philosophy of Emphasis; the Functions of the Fluid Wedge; the Birth of a Planet; the Laws of Riverflow. By D. T. SMITH, M. D., Lecturer on Medical Jurisprudence in the University of Louisville, Louisville; John P. Morton & Co., 1899. Pp. 9 to 263.

THIS title indicates the nature and scope of this little volume. It treats of subjects which have long occupied the writer, and they are of general interest. The essays are pleasingly written and thoughtful, and they contain many original suggestions and speculations.

BOOKS, ETC., RECEIVED.

The Newer Remedies. Including their Synonyms, Sources, Method of Preparation, Tests, Solubilities, Incompatibles, Medicinal Properties, and Doses as far as known, together with Sections on Organic Therapeutic Agents and Different Compounds of Iron. A Reference Manual for Physicians, Pharmacists, and Students. By Virgil Gollentz, A. M., Ph. D., Ph. D., F. C. S., Professor of Chemistry and Physics in the New York College of Pharmacy, etc. Third Edition, revised and very much enlarged. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. vi, 9 to 117. [Price, \$1.]

Twentieth Century Practice. An International En-

cyclopaedia of Modern Medical Science. By Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M. D. In Twenty Volumes. Volume XVI.—Infectious Diseases. New York: William Wood & Co., 1899. Pp. v-4 to 785.

International Clinics: A Quarterly of Clinical Lectures on Medicine, Neurology, Surgery, Gynecology, Obstetrics, Ophthalmology, Laryngology, Pharyngology, Rhinology, Otology, and Dermatology, and Specially Prepared Articles on Treatment and Drugs. By Professors and Lecturers in the Leading Medical Colleges of the United States, Germany, Austria, France, Great Britain, and Canada. Edited by Judson Daland, M. D. (Univ. of Pa.), Philadelphia, Instructor in Clinical Medicine and Lecturer on Physical Diagnosis in the University of Pennsylvania, etc. Volume I. Ninth Series, 1899. Philadelphia: J. B. Lippincott Company, 1899. Pp. ix-303.

The Twelve Tissue Remedies of Schussler, comprising the Theory, Therapeutic Application, Materia Medica, and a Complete Repertory of these Remedies, Homœopathically and Biochemically Considered. By William Boericke, M. D., Professor of Materia Medica and Therapeutics in the Hahnemann Hospital College, San Francisco, etc., and Willis A. Dewey, M. D., Professor of Materia Medica in the University of Michigan Homœopathic Medical College, etc. Fourth Edition, rewritten and enlarged. Philadelphia: Boericke and Tafel, 1899. Pp. 5 to 424. [Price, \$2.50.]

Traité de médecine. Deuxième édition. Publiée sous la direction de MM. Bouehard, Professeur de pathologie générale à la Faculté de médecine de Paris, et Brissaud, Professeur agrégé à la Faculté de médecine de Paris, etc. Tome I. Par MM. L. Guignard, A. Charrin, P. Le Gendre, G.-H. Roger. Avec figures dans le texte. Tome II. Par MM. A. Chantemesse, F. Vidal, L.-H. Thoinot, L. Guinon, E. Boix, A. Ruault, W. Ettinger, L. Tollemer. Avec figures dans le texte. Paris: Masson et Cie., 1898.

Twenty-third Year Book of the New York State Reformatory. For the Fiscal Year ending September 30, 1898.

The Treatment of Post-Operative Conditions. By Emory Lanphear, M. D., of St. Louis. [Reprinted from the *American Journal of Surgery and Gynecology*.]

Shock. By Robert H. M. Dawbarn, M. D. [Reprinted from the *Medical News*.]

Miscellany.

The Punishment of the Insane.—Dr. H. E. Allinson (*American Journal of Insanity*, April) says that closely connected with the question of punishment is that of responsibility. Punishment implies criminality, and these two terms should be divorced from insanity. The old idea of retributive justice appears to have taken firm root in the minds of men, and is hard to eradicate. The whole theory of punishment has undergone, and is still undergoing, radical changes. Even the sane are not subjected to a tithe of the penalties once imposed. The problem is to devise the best means to maintain law and order and protect the interests of society. It is true that the insane are both trouble-

some and dangerous. They have no right to disturb or threaten the peace of others. In hospitals we often remove such unruly elements from quiet wards to noisy and violent ones to insure freedom from annoyance for their associates. If the change results in the greater self-control of the individual, we are gratified. So also, if an insane person is threatening injury to himself, we should take steps to prevent it. Taking away privileges and liberties, however, is not punishment. By analogy, if a sane man fractures his leg, the limb is placed in splints and he is deprived of the pleasure of walking about. If he should become afflicted with a contagious disease, he is quarantined, not as a punishment, but to secure the health and comfort of others. The surgeon determines upon what conditions and when the injured man may walk, and the physician decides when it is safe for the patient to leave the hospital. The dangerous and criminal insane should be judged by a similar standard—namely, the question of their safety to be at large. It is the only criterion that can properly be established. An insane man may have to reap the consequences of his acts, but he should not be punished for them. Insanity, instead of excusing, often lays upon its victims a greater burden and carries with it a longer term of confinement than that imposed by law upon the sane. If the insane were to be held responsible for criminal acts, the majority of them would be imprisoned for brief and definite terms. Those, therefore, charged with dangerous assaults would soon be at liberty again to attempt to injure or to kill. We have a case in mind where an insane man committed a homicide and served a short term. After his release he killed a second victim and was again imprisoned, and upon his liberation again repeated the act; and still again for the fourth time. During his last imprisonment he was found to be insane, and was committed as a lunatic. He has now been detained fifteen years over his time in an asylum to which he should originally have been committed. To hold a woman responsible because she for a time could resist an insane impulse to kill her child but finally yielded, would be similar to reproaching one for succumbing to disease who, for example, should fight the inroads of pneumonia and walk about until no longer able to keep from bed. Society is better protected by the doctrine of irresponsibility. Let the dangerous and criminal insane be sent to a hospital, and the grounds be stated upon which they are declared to be irresponsible, and let them there be held in secure custody so long as such grounds exist. They should be weeded out from the community. Often they are depraved and degenerate. Actual experience has shown that the average length of confinement of persons charged with crime is greater in asylums than in penal institutions. The insane criminal should be placed in an asylum early in his career, not after having run the gantlet of several imprisonments and the commission of numerous crimes. We believe where mental disease exists associated with crime that a careful scrutiny should be made and such persons detained for prolonged observation, treatment, and care; a reasoning which seems eminently sound and is supported by analogy in every other form of disease which finally becomes prostrating to both mind and body.

Temperament as Indicated by the Teeth.—C. H. Nicholson, D. D. S. (*Dental Digest*, May), in a paper recently read before the Rochester Dental Society, said that in this interesting theme of thought much advance

had been made, but the subject did not receive the attention its importance demanded, and was too readily shelved as a hobby, to be ridden only on special occasions. Taking a brief survey, we found that the teeth of the bilious temperament were apt to be strongly colored, being of a bronze-yellow, large and angular, rather longer than wide, neither brilliant nor transparent, with slight translucency, the gums heavy and firm with angular festoon, the articulation closely locked, the corners nearly square, with proximal surfaces in contact a considerable portion of the distance from the cutting edge upward. The arch was nearly flat from one cusp to the other, and the lines from this point backward nearly straight. The dome of the palatine surface was high and nearly square, the rugæ heavy and of square formation, corresponding to the general outline.

In the sanguine we had a creamy-yellow color, beautifully rounded in proportion with well-developed cusps, the surfaces smooth, the edges and cusps translucent, round, and full festooned, set in a horseshoe-shaped arch, the dome high and round, with rugæ numerous and graceful. The jaw being inclined to rotate in mastication, the teeth articulated edge to edge, and were very often worn down to a level surface, the proximal surfaces being in contact for about half their length.

The arch of the nervous was pointed like a Gothic window, the incisors often overlapping, while the vault of the mouth was high and narrow. Articulation was not close. The teeth were pearl blue or gray in color, long and narrow, with fine cutting edges and cusps, brilliant surfaces, edges transparent and set in beautifully festooned gums, corresponding in delicate tracery to this, the artistic temperament.

The lymphatic gave us the large unshapely tooth of greater width than length, with cusps poorly defined and having an opaque, muddy color. The articulation was loose and flat and the gums thick, without beauty of outline. The arch was wide and semicircular in form, and the roof of the mouth low and flat and not particularly marked with rugæ.

The Intracranial Effects of Burns, especially in Relation to Legal Medicine.—At a recent meeting of the French Society of Legal Medicine, Professor Strassmann, of Berlin (*Gazette hebdomadaire de médecine et de chirurgie*, February 23d), communicated a somewhat delicate problem in medical jurisprudence. In a house that had been burned down there was found among the ruins the half-carbonized body of a woman forty-two years of age. The body lay on the left side, which was relatively unaffected, on a bed. The right side was completely consumed, and the bones denuded of soft parts. The right side of the face was equally carbonized, but the cranium was entire. On removal of the cranial vault there was found over the whole surface of the right hemisphere a reddish mass, dry, thick, adherent to the internal surface of the skull, and separated from the dura mater by a layer of thick, dry grumous cerebral matter, which had escaped through a rent in the dura mater of the left hemisphere in the neighborhood of the frontal lobe. The tear was rounded with ragged edges, the size of a mark piece. The reddish-brown mass found in the interior of the cranium bore the appearance of a clot of coagulated blood which had been subjected to a high temperature, and this was confirmed by microscopical examination. Its maximum thickness was about five millimetres, and it adhered firmly to the bone.

The cerebral matter found outside of the dura mater was altered and dried; in some parts it was a centimetre and a half in thickness. The cranial vault was intact. The husband of the victim was suspected of having killed his wife and set fire to the house, and the experts were asked whether the extrameningeal hæmorrhage was to be attributed to external violence inflicted before the fire, or if the latter was adequate to produce it; also information was sought as to the origin of the rent in the dura mater. On the last point the experts were of the unanimous opinion that the expansion of the gases in the interior of the cranium under the influence of heat was quite adequate to account for the condition. The former question was, however, more difficult, and most of the experts held that it had been caused by external violence, which it is known can produce rupture of the dura mater without injury to the skull. Professor Strassmann, however, considered the hæmorrhage also as an effect of combustion. He had, as it happened, recently made an autopsy on three cadavers burned almost to cinders in the explosion of a match factory. In one of them there was found between the cranium and the dura mater a thick brownish layer, resembling in all respects the one described, and consisting also of calcined blood. The fact of an explosion might certainly have suggested an external shock, but careful examination revealed around it the presence of drops of effused fat, whose total volume measured several cubic centimetres. This fat evidently came from the cranial bones, whence it had oozed as the result of heat, from which fact Professor Strassmann suggested that the blood might have had a similar origin from the bones and soft parts. He instituted, therefore, a series of experiments upon human cadavers and on the heads of animals, and found that whenever the head was exposed to a severe heat sanguineous exudation occurred on the inner table of the cranial vault. The following conditions were found to be necessary: 1. A local action of the flames on a limited portion of the cranium. 2. A flame sufficiently intense to carbonize the soft parts and profoundly attack the bone. 3. The cranium intact and not rent by the action of heat.

The United States' Example in the Matter of Hospital Ships Followed.—According to the *British Medical Journal* for April 29th, the example given by the United States during the Spanish-American war of fitting out an ambulance ship under the Red Cross regulations has been followed in Austria. The vessel has been named the *Graf Falkenhayn*, after the first president of the Austrian Red Cross Society. The new steamer, which has an estimated speed of nine knots, has an isolated wing for infectious cases, and two bath rooms, and is provided with all modern hygienic requirements. Its equipment, which is now complete, includes four lifeboats and two disjunctable rafts. The Austrian Red Cross Society is the first institution of the kind in Europe which possesses a permanent naval ambulance.

The New Anatomy. *Practical Medicine* for May has collected the following instances of the newer (literary) anatomy:

The murderers have discovered some astonishingly vulnerable parts of the human anatomy of late. From a paper this morning we learn that a Georgia colonel was "shot in the ticket office"; the other day a man was fatally shot "through his door," and not long ago another received a fatal wound "in his window."—*New York Commercial Advertiser*.

He kissed her passionately upon her reappearance.—*Jefferson Souvenir*.

She whipped him upon his return.—*Hawkeye*.

He kissed her back.—*Constitution*.

She seated herself upon his entering.—*Albia Democrat*.

We thought she sat down upon her being asked.—*Saturday Gossip*.

She fainted upon his departure.—*Lynn Union*.

He kicked the tramp upon his sitting down.—*American Pharmacist*.

We feel compelled to refer again to the poor woman who was shot in the oil regions some time ago.—*The Medical World*.

And why not drop a tear for the man who was fatally stabbed in the rotunda, and for him who was kicked on the highway? For all the above we are indebted to the *Medical Age*, but it fails to mention the fact of the woman being accidentally shot in the waterworks or the man injured upon the long bridge.—*Colorado Medical Journal*.

The New York Medical Gymnastic and Massage Society has been incorporated for the purpose of raising the standard of the practice of medical gymnastics and massage. Dr. H. C. Thompson is the president, and Dr. H. V. Barclay the secretary. There is an advisory board consisting of Dr. Thomas E. Satterthwaite, Dr. Andrew H. Smith, Dr. Leonard Weber, Dr. William T. Bull, Dr. George H. Woolsey, Dr. Henry L. Cochran, Dr. A. J. C. Skene, Dr. Clement Cleveland, Dr. T. Halstead Myers, Dr. Henry Ling Taylor, Dr. William M. Leszynsky, and Dr. Charles L. Dana.

The Jaw and its Uses.—According to the *Dental Digest* for April, in an address, James A. Reed, the prosecuting attorney of Missouri, said: "Now here are two professions living each by the jaw of man, yet distinguished in this: The lawyer uses his own jaw as a weapon of attack and defense; the dentist attacks the jaw of another with a weapon, and there is no defense. The dentist uses the jaw as an end; the lawyer, as a means to an end. Observe, too, the interdependence of these two professions. For if the jaw is the lawyer's weapon, then the dentist who keeps this weapon in good working order becomes a *particeps criminis*, and this is probably the toughest thing ever said of any dentist, living or dead."

The Administration of Chloroform in the Street.—*The Lancet* for May 20th, in a letter from its Berlin correspondent, says:

"A curious event—the administration of chloroform in a public place—happened lately in Berlin. A woman, in trying to jump from an electric tramcar running at full speed through the Friedrich-strasse, fell and her right foot was caught between the platform and a wheel. Police and firemen made long but fruitless attempts to extricate the woman, who screamed piteously. Medical help was then sought at the neighboring university-hospital, from which a surgeon and two assistants were sent. The surgeon decided to administer chloroform in order to facilitate the work of rescue, and did so in the busy thoroughfare and in the presence of a great crowd. The tramcar was raised with lifting jacks, and when, after more than an hour, the woman was released from her terrible position with comparatively slight contusions, the surgeon was loudly applauded by the spectators."

Sacra Fames.—The leech is great on "low diet." Having got a poor mortal in his clutches with typhoid fever, after many weary days of starvation (for the patient) he relented and said: "Well, my friend, would you like a small chicken to-day?" "Indeed I should," replied the invalid. "Well," said the leech, "what shall it be stuffed with?" "Another chicken, please, sir," replied the empty one.—*Echoes from a Mining Camp*.

A New Combined Vaccine Point and Scarificator.—Dr. L. A. Denis, of West Hoboken, New Jersey, has been kind enough to send us a specimen of a vaccine point resembling the ordinary ivory lancet-shaped point, pierced longitudinally by a needle the free point of which, extending somewhat beyond the vaccine blade, serves as a scarificator.

To a Delinquent Patient.—*The North Carolina Medical Journal* for May 20th quotes the following from the *Gross Medical College Bulletin*:

If I should die to-night—

And you should come to my cold corpse and say,
Weeping and heartsick, o'er my lifeless clay;

If I should die to-night—

And you should come in deepest grief and woe,
And say, "Here's that ten dollars that I owe,"
I might arise in my great white cravat
And say, "What's that?"

If I should die to-night—

And you should come beside my corpse to kneel,
Clasping my bier to show the grief you feel;

I say if I should die to-night—

And you should come to me, and there and then
Just even *hint* 'bout paying me that ten,
I might arise awhile—but I'd drop dead again.

The "Ophthalmotrician."—The following resolutions, presented by Dr. Louis J. Lautenbach, of Philadelphia, and supported and seconded by Dr. S. S. Towler, of Marionville, were unanimously adopted by the Medical Society of the State of Pennsylvania, on Wednesday, May 17th:

Resolved, That it is the opinion of the Medical Society of the State of Pennsylvania that opticians are not qualified by their training nor are they legally qualified to perform the work of the oculist, and they should not be the consultants of regular physicians. Further, it is

Resolved, That all physicians are requested to call their brother physicians in consultation, thus discountenancing the growing pretenses and assurances of the optician and his brother, the graduate optician, or, as he is beginning now to call himself, the "ophthalmotrician."

It is Dr. Lautenbach's praiseworthy purpose to present similar resolutions, substituting American Medical Association for Medical Society of the State of Pennsylvania, for adoption by the American Medical Association at Columbus, on Tuesday morning, June 6th.

Liquefied Air and Hot Rooms.—According to the *North Carolina Medical Journal* for May 20th, liquefied air has been suggested as a possible means of cooling the sick room in hot weather.

The Death of Dr. Georges Assaky, of Bucharest, is announced as having taken place on April 22d. He was forty-four years old.

Original Communications.

SOME REMARKS UPON
OBSTETRICS IN PRIVATE PRACTICE.*

By J. CLIFTON EDGAR, M.D.

IN an age of brilliant surgical operations, of bacteriology and serum therapy, we are prone to lose our interest in those procedures which form part of the routine work of the general practitioner. My excuse for bringing such a time-honored subject as the above before this society is the firm belief that the last word has not yet been spoken about so prosaic a topic as the management of normal labor.

I believe I am correct in stating that the general practitioner and obstetrician are too apt to consider only mortality in their results, and to pass over entirely the question of morbidity. Even to-day in midwifery the influence upon morbidity, the ultimate consequences of a mild puerperal septic process, are too apt to pass unrecognized by the obstetrician, until his case passes into the hands of the gynecologist for the cure of chronic uterine and circumuterine inflammation, which had its origin in some lapse from true aseptic principles during the management of what we are pleased to term normal labor.

We hear daily of a reduced mortality and little or nothing of a lowered morbidity rate. It is with the object of referring to some of the lapses from aseptic principles and the means to avoid them in the management of normal labor that this paper is presented this evening.

We start out with the premise that the whole process of labor, properly considered, is a conservative process whose tendency is to prevent sepsis, and it should be our aim not to thwart this process or supplant it by methods of art, but to follow and aid it, only interfering when for one reason or another the resources of Nature prove insufficient.

Recently the writer received the following letter of inquiry, which bears directly upon the subject:

WILMINGTON, D. C., December 1, 1898.

"MY DEAR DOCTOR: Will you kindly advise me regarding the following points:

"1. Do you refer your patients to some dealer from whom they can procure an obstetric outfit, or do you instruct each patient how to prepare and sterilize vulvar napkins, abdominal binders, surgical dressings, etc.?"

"2. What obstetrical bag do you advise; has it a sterilizer and lamp combined, where can such a bag be obtained, the price, etc.?"

"3. What is the best way to keep records of obstetrical cases?"

"Thanking you in advance, believe me

"Very truly yours,"

In order to bring out the suggestions I desire to emphasize, I do not think we can do better than take the above letter as our text.

1. *The Obstetric Outfit.*—Shall the obstetric outfit be prepared by the patient or nurse, or shall it be procured already prepared from some dealer in surgical dressings?

A further question naturally suggests itself—namely, of what does the obstetric outfit to-day consist?

Aside from the "mother's outfit," meaning the clothes she will need during her lying-in period, and the "baby's outfit," including, if possible, a "baby basket," the obstetric outfit should at least include the following articles:

1. A douche pan, preferably square and of enamel or agate ware.

2. Two ordinary rubber blankets, or two pieces of rubber sheeting, one one yard square and the other two yards square.

3. Three or four dozen soft napkins for vulvar dressings, or the same number of vulvar pads from a surgical-dressing dealer.

4. One or two pounds of sterilized absorbent cotton, or twenty-five yards of cheese cloth or sterilized gauze. This for sponging.

5. Six abdominal binders of soft muslin or mull, eighteen inches wide and preferably made to fit the figure at the sixth month of gestation.

6. Two hand brushes.

7. Some old linen for the baby's eyes and mouth.

8. Four ounces of tincture of green soap.

9. Bottle of sublimate tablets.

10. Seven ounces of chloroform.

11. Four ounces borie acid, powdered.

12. One tube of sterile white vasoline (for the baby).

13. Small and large safety pins and bank pins.

If there is no nurse available before labor sets in, and it is necessary for the patient to see to the cleansing of the above articles, she may be instructed to pin the douche pan, rubber sheeting, and hand brushes separately in coarse kitchen towels and boil for half an hour in an ordinary wash boiler. The articles so boiled are then dried without removing the towels, put away, and not opened until the time of labor.

The soft napkins, if these are to be used for vulvar dressings, should, freshly laundered, be pinned, half a dozen in a package, in coarse kitchen towels and put away until the onset of labor. The nurse is then instructed to sterilize one package at a time by sponging in the oven until the outer cover is thoroughly dry. For sterilizing instrument, and disinfecting the skin of the kitchen range, one only need place them in water graduated to 200° C., so as to prevent the water from rising too high, and to make sure that 200° C. is obtained. The absorbent cotton, the old linen for the baby's eyes, and

* Read before the Society of Alumni of Bellevue Hospital, 1898.

the cheese cloth are treated in the same way, the two latter being cut up into convenient pieces and sterilized as needed. It is sufficient that the abdominal binders be thoroughly laundered and pinned separately in freshly laundered towels until needed.

Further articles to be in readiness at the time of labor, and obtainable in most households, should include:

Articles to be in Readiness at Time of Labor.—1. Arrangements for an abundant supply of hot water.

2. A bowl for vomited matter.

3. Two clean earthen, agate, enamel, or paper ware bowls for hand cleansing.

4. A clean bowl for the placenta.

5. Three pitchers: one for boiling water, one for cold boiled water, and one for mixing antiseptic solutions.

6. A clean cup or tumbler with boric-acid solution and gauze or old linen wipes for the baby's eyes.

7. A half dozen freshly laundered old linen sheets to serve as bed pads or pilches.

8. An abundant supply of freshly laundered sheets and towels.

9. A change of night clothing, warmed, for the mother.

10. A warm blanket to receive the baby.

Of these articles, the four bowls, the cup, and the three pitchers should be scrubbed with soap and water and boiled in a wash boiler, or at least scalded out.

It is sufficient that the old sheets to be used as bed pads and the usual bed sheets and towels are freshly laundered.

For special cases, however—for example, breech presentations—it is desirable that half a dozen towels are sterilized by boiling or by dry heat in the oven, as described above.

It will be noticed that the time-honored douche bag and tube have not been referred to, and this is because we do not employ douches except for a positive indication; and, further, because we believe these articles should be part of the physician's obstetric outfit, sterilized and cared for under his direct supervision. I know of no reason why a patient, be she ever so wealthy, should purchase an instrument which *may* be needed, and, like other surgical appliances, should only be used by the physician himself, or under his direct supervision. For it is my firm conviction that, both from the clinical and bacteriological standpoint, an intra- or post partum douche, be it never so carefully administered, carries with it a distinct risk of infection, and in case a responsibility which should not be lightly assumed.

Most or all of the articles contained in the above list of the "obstetric outfit" can to-day be obtained, sterilized in their final wrappers and ready for use, from many of the dealers in surgical dressings, notably Van Horn & Co., New York; Kalish, New York; Johnson

& Johnson, New York; and Fraser & Co., New York, at prices for the outfit varying from four to thirty dollars.

These obstetric outfits, cleansed and sterilized, are usually packed and sealed in a neat box, thus allowing the contents to be kept intact until needed.

The contents of these outfits vary somewhat in detail, but the following list contains the essentials:

Obstetric Outfit.—1. Agate-ware (square) douche pan.

2. Sterilized bed pads.

3. Sterilized vulvar pads.

4. Sterilized absorbent cotton.

5. Sterilized absorbent gauze.

6. Two pieces of rubber sheeting or two ordinary rubber blankets, one for permanent labor bed and the second for the draw sheet.

7. Abdominal binders.

8. Glass and rubber catheter.

9. Scrub or hand brush.

10. Sterilized tape for cord.

11. Sublimite tablets; boric acid powdered; chloroform; ergot; borated talcum powder; soap; tube of sterile vaseline; safety pins.

II. An Aseptic Obstetric Case and Sterilizer Combined.—For over a year I have been experimenting with different patterns of bags and cases in order to fulfill the requirements of private practice. I have always looked upon leather obstetric bags with suspicion and fear, because of the difficulty of cleansing them, and because articles to be used in the lying-in room can not be safely carried in them unless such articles and instruments are boiled immediately before use. Further, we believe that the ordinary leather obstetric bag which has been from one case to another, in cabs and street cars, which of necessity has had its interior soiled by bloody fingers and instruments, green soap, ergot, or other drugs, has no place in the lying-in room in the present age of aseptic surgery. Leather obstetric bags, therefore, can not be recommended, because of the difficulty, if not impossibility, of cleansing them. I have recently (December 20, 1898) had cultures taken from the interior, especially the corners and angles, of six obstetric leather bags, in the bacteriological laboratory of the Cornell University Medical College, and, although the results as reported from these cultures proved negative, such evidence, of course, is insufficient.

Linen obstetric bags which can be boiled or sterilized by steam have been used in Germany.

Dührssen has used an asbestos bag, which can be sterilized by dry heat with the instruments *in situ*.

Aluminum I have experimented with, but find unsuitable by reason of the uncertain composition of the metal.

The ideal obstetric case is one made entirely of metal, which will permit of cleansing by dry heat, steam, or boiling. Such a case may be contained for transport-

tation in a suitable holder or bag. The bag-shaped cover is preferable because more convenient and conventional.

The great disadvantage of a metal case, in addition to its greater cost, is its additional weight.

The aseptic metal obstetric case, which I here recommend, is the result of much experimenting, and weighs but six pounds more, including leather holder or case, than an ordinary leather obstetric bag. The weight of the case complete, with glassware filled and including a Tarnier forceps, is twenty-five pounds.

This increased weight can be further reduced some two pounds by the use of lighter metal in the manufacture of the case.

From actual experience over a period of several months we believe that the inconvenience of the additional five or six pounds is more than overbalanced by the many advantages of such a case, not the least of which is cleanliness.

The case practically consists of two trays, male and female, made of sheet iron and enameled in white at a temperature of several hundred degrees (Fig. 1). The male or larger tray measures $17 \times 8 \times 6$ inches, partially fits into the shallower female tray ($17 \times 8 \times 3\frac{1}{2}$ inches), leaving a space of two inches, in which space is contained a third tray made of canvas, with loops and compartments to contain the glassware of the case

simply dropped over the trays, and straps prevent the latter from falling out (Fig. 1). A more elaborate holder is one made on the ordinary bag plan, but without bottom other than one-inch side flaps; this also

FIG. 2.—Smaller female tray above, containing canvas tray, with cover of latter thrown back to expose its contents; larger male tray below, with some of its contents showing. (From photograph.)

FIG. 1.—Leather holder of case above; below, male and female trays, with some of the contents of the former. (From photograph.)

(Fig. 2). A leather holder or case covers both trays when fitted together, and strong straps hold it firmly together. Two leather holders are made. The simplest and cheapest is one with opening below, which is

drops over the trays and is strapped in place. The top of this holder opens as an ordinary bag, thus obliterating all but lateral corners, and allowing of thorough cleansing.

My objects in having the case thus made of two trays, one large and the other small, and both enameled at a high temperature, with an inner canvas tray to contain the glassware, are as follows:

1. The case is aseptic. The case proper can always be rendered sterile before being taken to a confinement case by either boiling, baking in an ordinary kitchen oven, or by steam under pressure, as the size of the case permits its being sterilized in the medium-sized steam sterilizer of the market. No matter what the character of the case attended, be it ever so septic, or instruments, douche bag, catheter, gown, etc., ever so soiled with pus and blood when thrown into the case to be carried home, the entire outfit can be placed in a wash boiler and rendered sterile in a short period of time by boiling.

2. Such a case furnishes a neat table, after the canvas tray is removed from the smaller tray and the contents from the larger, with two handy receptacles which may be put to a most convenient use and will often prove most valuable and convenient. For example, aside from a supply of water, a small tin of carbolic acid, and more need be supplied, the case, in case of confinement than the case and trays, and the larger tray, which holds, when half full of water, may be used to wash the hands and face, and to pour water and

the smaller female tray, which holds when half full three quarts, to disinfect the hand and forearm in sublimate solution.

3. The length of this tray (seventeen inches) permits of the entire forearm being submerged in the sublimate solution, an advantage that will quickly be appreciated by the surgeon (Fig. 3).

4. The writer is in the habit of using the smaller female tray as a sterilizer. The obstetric forceps I boil just before using it. It is after use scrubbed with soap and hot water and a hand brush by my office nurse, then boiled in an ordinary fish kettle, wiped dry, pinned in a freshly laundered towel, and placed with the other articles in the case ready for the call.

When in the course of labor indications point to the use of forceps, the instrument, still pinned in the towel, is placed in the smaller tray of the case, and sent to the kitchen to be boiled for an hour. The boiling water is poured off in the kitchen, and the forceps, still in its towel, is brought in the tray to the bedside, and the towel is only removed after the patient and the operator's hands have been prepared for operation.

5. The larger tray, again, by reason of its size, makes an excellent bath in which to plunge an asphyxiated child, and one has always at hand a convenient bath tub in which a modified Byrd's method of artificial respiration can be carried on, the child being meanwhile submerged in very hot water (Fig. 4).

6. The advantages of the inner canvas tray, which rests in the space between the two metal trays, will be readily appreciated (Fig. 2). This tray is practically a canvas case, measuring $17 \times 8 \times 2$ inches, with a lid, and canvas handles at either end to lift it out of the smaller metal tray (Fig. 2). My object in using canvas here, with a separate loop or compartment for each piece of glassware or instrument, was to secure a noiseless tray for this part of the physician's obstetric outfit, one in which the articles are all in plain sight, so as to be selected at an instant's notice, and one, moreover,

over it in bold type and indelible ink the name of its contents, so that any desired article can be selected at a glance and the absence of any article readily detected. Until one has actually used such an arrangement of the

FIG. 4.—Large male tray used as a bath for an asphyxiated infant. (From photograph at Emergency Hospital.)

physician's obstetric outfit at the bedside no description can possibly convey the convenience and satisfaction of having everything necessary for an emergency or ordinary labor thus spread out before one, all labeled and contained in an aseptic case.

7. The case as a whole is readily converted into an ideal obstetric operating case by the addition of the desired instruments pinned in towels and placed in the larger of the two trays, for which purpose sufficient room has been provided. The length of the large tray permits of Tarnier's forceps, a cranioclast, and cephalotribe being carried in it.

Contents of the Case.—a. In large male tray:

1. Clean apron.
2. Kelly pad.
3. Canvas lithotomy sling.
4. Four-quart sterile douche bag (pinned in towel).
5. Metal receptacle containing sterile vaginal and douche tubes and glass catheter.
6. Volsella, dressing, needle, and tongue forceps and scissors (pinned in towel).
7. Obstetric forceps (pinned in towel).
8. Sterile cotton and plain gauze.
9. Five-per-cent. iodoform gauze.
10. Two sterile nailbrushes.

The two metal and the one canvas tray having been cleansed by boiling or dry or moist heat, as already described, each of the various articles contained in the above list is cleansed in a different manner in order to secure surgical cleanliness.

1. The apron is simply freshly laundered.
2. The Kelly pad is usually cleansed by my office

FIG. 3.—Small female tray used to submerge hand and forearm in sublimate solution. (From photograph.)

that can be repeatedly, cleansed by boiling whenever soiled by bloody fingers, soap, vaseline, or ergot. The principle of "a place for everything, and everything in its place," is here adhered to. Each loop has stamped

nurse with laundry soap, hot water and brush, and finally with a 1-to-20 carbolic-acid solution; should the pad be used about a case where a suspicion of sepsis exists, it is boiled for half an hour.

3. The Kelly canvas lithotomy sling is made of canvas, galvanized iron rings, and brass buckles, and is always boiled for half an hour after use.

4. The four-quart douche bag and tubing are, after use, scrubbed with hot water, soap, and a brush, rinsed in clean hot water, pinned in a clean towel, and boiled for half an hour. The towel and bag are then allowed to dry in an enamel-ware vessel over the kitchen range, and when dry are placed in the case.

5. The metal receptacle containing the glass douche tubes and catheter is boiled together with the lithotomy sling and douche bag. Both metal receptacle and glass tubes are first, however, scrubbed in a hot soda solution with soap and a brush.

6. The volsella, dressing, needle, and tongue forceps and scissors are, before being pinned in the towel, simply scrubbed in hot soda solution with soap and brush, and then dried, as they are intended to be sterilized by boiling at the residence of the patient.

7. The obstetric forceps is treated in the same manner as the foregoing.

8. The sterile cotton, plain gauze, and iodoform gauze I am accustomed to procure already sterilized from a dealer in surgical dressings.

b. In canvas tray contained in small female tray:

1. Green soap (sterile).

2. Vaseline (sterile).

3. Gauze eye sponges (sterile).

4. Gauze cord dressing (sterile).

5. Chloroform.

6. Ergot.

7. Strong acetic acid (99.5 per cent.).

8. Sublimate tablets.

9. Fine boric acid (sterile).

10. Normal saline powders.

11. Silver-nitrate solution (one per cent.).

12. Tape for cord (sterile).

13. Silk and gut ligatures and needles (sterile).

14. Soft-rubber catheter (sterile).

15. Umbilical scissors.

16. Medicine dropper.

17. Nail cleaner.

18. Safety razor.

19. English catheter (No. 16) with stylet.

20. Safety pins.

21. Sterile gauze bandage for sling.

22. No. 8 soft braded catheter opening at end.

23. Spring scales.

1, 2, 3, 4. The green soap, vaseline, gauze for eye sponges, and cord dressing are contained in one ounce screw-top ointment pots, and are sterilized by placing on the tray of a steam sterilizer.

5, 6, 7. Excepting the small two drachm bottle of

silver nitrate, there are but three bottles in the entire case.

These bottles are for chloroform, ergot, and acetic acid, and contain four ounces of the first and one ounce each of the last two. The bottles are glass-stopper and metal-cap safety bottles, and are especially made as reliable containers of chloroform, ergot, tincture of iodine, or carbolic acid for medicine cases and bags, as they are equally tight and free from leakage when resting longitudinally. The bottle is of heavy flint glass, with emery-ground glass stopper fitted accurately in the neck, and the stopper is kept in place by the metal cap, which firmly screws over the stopper and around the neck of the bottle, thus preventing any possible chance of the stopper becoming loose, and reducing the liability of leakage, if any, to a minimum. Experience has taught me that in addition to the cork supplied as a cushion in the top of each metal cap, a small quantity of absorbent cotton holds the glass stopper more securely. The advantages of such bottles in an obstetric case are sure to be appreciated after actual experience with them. We carry in the case Squibb's chloroform and Squibb's fluid extract of ergot, the latter for administration both by the mouth and with the needle. We use also Squibb's acetic acid, carrying the stronger preparation (99.5 per cent.). One ounce of this strong acid is sufficient to make several quarts of a 1-to-100 solution of acetic acid, which is the strength we make use of for vaginal and intra-uterine irrigation.

8. The sublimate tablets are contained in one-ounce glycerin-jelly jars with screw tops, each jar being capable of containing about thirty tablets of the size to make in a pint of water a 1-to-1,000 solution. The jars are "wide-mouthed," easily cleansed, strong, and of convenient size.

9 and 12. The boric acid, powdered, for dressing the stump of the umbilical cord or the baby's eyes, and the tape for the cord are contained in half-ounce screw-cap glass tubes, and both are sterilized by placing on the tray of a steam sterilizer.

10. The powders, three in number, for making a normal saline solution are contained in one-ounce glycerin-jelly jars. Each powder is sufficient to make one quart of the solution and has the following formula:

R Sodium carbonate gr. xv;

Sodium chloride 5 jss.

The powders are wrapped in paraffin paper, and, as the jar is practically air-tight, the powders are always ready for use.

11. The silver nitrate solution (one per cent.) for the baby's eyes, in a two drachm phial, is packed in absorbent cotton in one of the one-ounce glycerin jars. Even should the inner bottle leak or break, we still have the cotton and the outer jar to prevent leakage.

13. Silk and gut suture, cervix and perineal needles, are carried ready sterilized in a two-ounce and a-half screw-cap tube.

14. A No. 10 soft catheter is carried sterilized ready for use in another tube.

15, 16, 17. The umbilical scissors, medicine dropper, and nail cleaner are carried in loops in the lid of the canvas case. The medicine dropper is boiled and the scissors are sterilized in an alcohol flame at the bedside. After use, they are scrubbed in hot soda solution, with soap and brush, dried, and returned to the case.

18. A safety razor for shaving the vulva before forceps operation or version is also to be found in the canvas tray. In its tin case it takes up almost the same amount of space as a one-ounce glycerin jelly jar.

19, 20, 21, 22, 23. In the space in the middle of the tray is found room for a No. 16 English catheter, with stylet, for use to carry slings, or replace the cord or arm; safety pins; a sterile gauze bandage to use for slings in version; a No. 8 Lisle-thread braided catheter, with opening on the end, to clean out the baby's throat, and for a spring scale to weigh the baby.

Obstetric Operating Case.—For an operating set add to labor case the following:

1. Braun's cranioclast.
2. Dubois's scissors.
3. Smellie's perforator.
4. Three artery clamps.
5. Perineal retractor.
6. Tarnier forceps.
7. The above six pinned in towels and sterilized.
8. Scalpel and blunt bistoury.
9. Ether.
10. Rubber apron.
11. Sterile gauze bandages for slings.

FIG. 5.—Plan to illustrate use of the obstetric case at the bedside.

Use of the Case at the Bedside. It is recommended in the use of this obstetric case at the bedside that the leather cover be removed in another room or the hall, and only the enamel ware tray, carried into the lying-in room. A small table is selected, placed at the head of the bed, on the side selected for vaginal examinations and delivery. The table is covered with two or three

freshly laundered towels. The large male case is lifted out of the smaller female tray and placed, with its contents undisturbed, at the distal end of the table (Fig. 5). The canvas tray is then lifted out of the small female tray and placed with its lid thrown back next to the large tray, and, lastly, and nearest the physician, is placed the small female tray ready for the sublime

solution. If it is desirable to use the larger tray for hand washing, the articles contained in it may be arranged conveniently upon another portion of the table. Ordinarily, we do not disturb the contents of the larger tray until needed, and use running tap water for hand cleansing with soap and water (Fig. 5).

The nail cleaner, green soap, and one of the hand brushes are now taken to the nearest tap of hot and cold water or to a basin of hot water, the coat removed and sleeves rolled to the elbow, nails cleaned, and hands and forearms scrubbed and rinsed free of soap. Returning to the bedside, the clean gown is put on, the remaining hand brush dropped into a solution of 1-to-2,000 sublimate in the smaller tray, and the hands and forearms scrubbed in this. The patient having been prepared for vaginal examination and confinement, these are carried out forthwith. As labor goes on, the various articles are taken from the canvas and large tray as needed. Sterile cotton and plain gauze are at hand as needed for sponges in any of the three stages; the Kelly pad for the rupture of the membranes or the second and third stages, or vaginal douches; the sterile douche bag and glass tubes for irrigation; the sterile vaseline for lubricating the fingers, if one desires to use it; chloroform for administration in second stage; sterile gauze sponges to wipe the baby's eyes and mouth out on the expulsion of the head; sterile tape to tie the cord; sterile dressing for the same; clean scissors to cut the same; nitrate of silver for the eyes; ergot for the end of the third stage, or hemorrhage, as well as acetic acid for the latter,

and a soft catheter to aspirate the baby's larynx. Should complications occur, we have a sterile lithotomy sling and the Kelly pad for drainage at the side of the bed; a safety razor to shave the vulva; a catheter to empty the bladder; a volsella and dressing forceps and iodoform

either the larger or smaller tray and sent to the kitchen to be baked or boiled.

The case is made by Messrs. Charles Reynders and Sons, Twenty-third Street and Fourth Avenue, New York.

III. *Keeping Records of Obstetric Cases.*—We have nothing new to offer in the method of recording and preserving histories of obstetric cases in private practice, other than a compact, inexpensive card-index system. We have at various times in the past used the ordinary history sheets and history books for this purpose, but experience has proved the card system to be most satisfactory, because simple, orderly, and self-indexing. The cards we use are, as recommended by Dr. Robert L. Dickenson, of Brooklyn, of standard size ($6 - 6\frac{1}{8}$ inches), and are obtainable of the two largest card-index makers

FIG. 7.—Reverse of pregnancy card; upon this side of the card are recorded the results of the various urinary examinations of pregnancy, as well as treatment or remarks.

gauze to pack the uterus; needle forceps, needles, scissors, silkworm and catgut for lacerations of cervix or perineum; an English catheter to replace a prolapsed cord; a tube to give intra-uterine irrigations and sterile bandages to use as slings for versions.

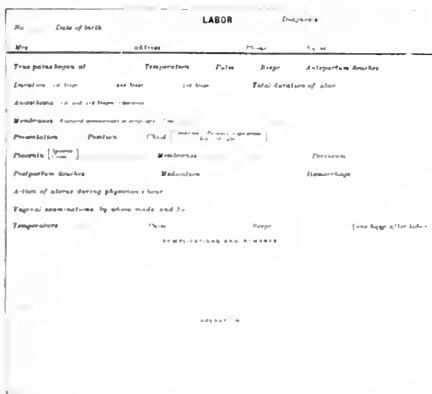

Fig. 8. Labor and performance card upon this side of the card is recorded the history of labor should no room be required for history of complaints or operations; a diagnosis block card of 12 by 10 is used in addition.

If major obstetric operations are demanded, we add to the above case the list of instruments already enumerated.

If at any time in the course of labor the forceps, perineorrhaphy, or uterine packing set appear indicated, they are, in their original wrappings, placed in

FIG. 9. Reverse of Fig. 8—record of puerperium and examination of the patient at the end of puerperium and attendance.

of this city—namely, the Library Bureau, 280 Broadway, and Globe Company, Fulton and Pearl Streets. Such cards are elastic and portable and can be readily used at the bedside or operating room, for, when doubled, the history of the patient can be readily carried in the pocket or card case.

For indexing and preserving the cards, an oak tray with cover, the latter one third the height of the box, and the whole to contain a thousand cards, is convenient. Any of the different methods of indexing the cards may be used. For obstetric use, we utilize three printed cards: The first, pregnancy (Figs. 6 and 7), the second, labor (Fig. 8) and puerperium (Fig. 9), and the third, a diagnosis card (Fig. 10), which is printed on a blank and is used for complications and, with the first two cards, prove sufficient to cover the whole history.

The observations to be noted are: (1) the number of firms (6 and 7), labor (Fig. 8), and capital (Fig. 9) have been carefully selected, (2) the owners of most of many years' experience in the textile industry, (3) a good industry record, (4) of course, the data is selected to ob-

stetrics, for the same case with the blank "diagnosis" cards (Fig. 10) may be applied to general medicine and surgery.

I am in the habit of urging upon my students the importance of starting some such method of history-taking in order that they may subsequently profit from a study of their cases. Should the physician not take up some methodical system of recording his cases at the outset of his practice, he is not likely to do so later. Of course, it is not always pleasant to acknowledge one's errors upon paper, but one can learn as much or more from a subsequent study of such errors as from successes.

Method of using the History Cards.—As already stated, there are only three printed cards in the case, as labor and the puerperium are contained upon one card. For convenience in indexing and selecting, we use three colors—blue for pregnancy, salmon for labor and

buff diagnosis card, and given a number referring to the detailed account of the case, written on the usual bedside history charts, which latter history sheets are filed in large letter-file boxes. The buff abstract card is then indexed alphabetically with the other cards.

At the completion of the puerperium, the labor and puerperium card is returned to the box. At the end of the year, or other convenient time, all cards belonging to a given case are fastened together with a brass clip and indexed among the alphabetical guides at the distal end of the box. We use the "Niagara clip," which securely holds the thinnest piece of paper and does away with pins and other puncture fasteners. For obstetric cases seen in hospital or consultation work, we carry to the case the three cards, folded, in the pocket, and make the observations in the operating room or at the bedside.

50 EAST THIRTY-FOURTH STREET.

QUANTITATIVE DETERMINATION OF ALBUMIN IN THE URINE.

By CHARLES W. PURDY, M. D., LL. D.,

CHICAGO.

ALTHOUGH fairly accurate and ready methods of detecting the presence of albumin in the urine have been known and practised for over a century, yet it can not be said that any of our present methods for quantitative estimation of albumin in the urine are in any degree satisfactory for practical clinical work. The gravimetric method requires so much time and labor to reach trustworthy results that it is altogether out of the question for daily work. The volumetric method of Esbach requires twenty-four hours' time to reach results, which in the end can not be said to be uniform or satisfactory. The coarser volumetric methods, as coagulation by heat or other agents and standing aside in graduated tubes for measurement, give no uniform or exact results that can be taken as a safe guide in clinical work. In addition to this, the present lack of a uniform method of expressing quantities of albumin in the urine by the different methods has rendered the whole subject confusing and misleading not only to the student but often to the clinician. Thus we hear and read of the expression "percentage of albumin in the urine" as applied indifferently to gravimetric and volumetric measurements, as though they were synonymous in significance, when, as a matter of fact, the differences between the two are so widely apart as to be absolutely misleading unless the proper distinction is made. Thus it is no uncommon thing to note in the urine the presence of twenty or thirty per cent. of albumin expressed volumetrically. Such a percentage by actual weight would be a physical impossibility, because the amount of albumin in the blood serum itself never exceeds nine per cent.; and it would therefore be clearly impossible for the proteid contents of any fluid derived

FIG. 10.—Blank card ruled; used as extra card in pregnancy, labor, or puerperium, or as index card for general non-obstetric subjects.

puerperium, and buff for the diagnosis or blank card. The pregnancy cards I keep in the proximal end of the case, by themselves, until finally indexed, and they constitute during this time an index of cases of expected confinement. Upon seeing a case of pregnancy in the office or at the patient's home, the pregnancy card is made out and returned to its place in the box, and becomes a record of a case of an expected confinement. Upon the receipt of the first specimen of urine, the analysis, with date, is recorded upon the back of the card, as well as any subsequent treatment or remarks upon the case. Upon being called to a case of labor, one selects the proper pregnancy card and a blank labor card to take with him to the case. During or after labor, the labor card is filled in and left at the case for the nurse to record the observations of the puerperium of both mother and child, the pregnancy card being returned to its place in the case.

Should the labor or puerperium prove complicated, requiring more space, the history is abstracted on the

directly from the blood to exceed the albumin in the blood serum itself. As a matter of fact, the amount of albumin in the urine, expressed gravimetrically, rarely rises above two and a half per cent., and perhaps never exceeds three per cent. It is therefore obvious that at present we lack a ready, trustworthy, and convenient method for the determination of albumin in the urine, coupled with more exact and definite methods of expressing results obtained. A method embracing these essential features as its basis should lend valuable aid in clinical observation, and tend to greater precision in the therapeutics of albuminuria, both of which are greatly needed.

With these objects in view, about five years since I began experimental investigations of the subject, and within the last year I have been enabled to bring my investigations to a satisfactory conclusion. In brief, the method finally adopted and now brought forward consists in precipitation of the albumin by a uniform method, uniform measurement of the same volumetrically by means of the centrifuge, the determination of the actual relationship between volumetric and gravimetric percentage, and finally the establishment of a table for practical work that expresses these relations in detail. In order to harmonize the different methods of expressing quantities now in vogue, the table is made to show the volumetric percentage, its corresponding gravimetric value of dry albumin, and the corresponding number of grains of albumin to the fluid ounce.

A number of methods of determining the quantity of albumin in the urine volumetrically have been devised upon the principle of precipitation by reagents and allowing a definite time for packing by gravitation, and some of these have been much in vogue in clinical work. It requires but little exact observation, however, to show that results thus obtained are very far from being uniform or accurate when compared with those obtained gravimetrically, and therefore they are misleading. The force of gravitation, which is depended upon for uniform packing, is inadequate to overcome the lesser forces which arise from varying conditions in the test and its physical surroundings. Thus the slow chemical changes progressing between the reagents, or between these and the urine, or even in the latter itself, are often sufficient to liberate enough gases to completely counterbalance the force of gravitation, and the albumin rises as a consequence *en masse* to the surface. Thus, indeed, often occurs with Esbach's test, heretofore so much employed. In a less degree the quantity of albumin present, the specific gravity of the urine, and the surrounding temperature furnish disturbing influences by opposing forces to that of gravitation, and thus prevent uniformity of results. In short, gravitation is altogether too feeble a force to secure uniform volumetric measurements of bodies whose atomic weights are as light as those of the proteid group. Fortunately, the

introduction of the centrifuge has rendered it not only possible but practicable to largely neutralize the opposing forces to volumetric measurement of many constituents of the urine—albumin included—and this is accomplished by the substitution of a force many hundreds of times greater—viz., centrifugal force. In addition to this, by the same means we are enabled to shorten the time of analysis from twenty-four hours to fifteen minutes, thus bringing the process easily within the requirements for practical clinical work.

The method worked out in my laboratory and herewith brought forward for practical use consists concisely and briefly as follows: Precipitation of the albumin in carefully graduated percentage tubes (fifteen cubic centimetres capacity) by means of two cubic centimetres of fifty per cent. acetic acid, and three cubic centimetres of a ten-per-cent. solution of ferrocyanide of potassium added to ten cubic centimetres of the urine. After mingling the reagents with the urine, the whole should stand for ten minutes to insure entire precipitation of the albumin. The tubes should next be placed in a centrifuge, the radius of which should be exactly six inches and three fourths, and the centrifuge should be operated at fifteen hundred revolutions per minute for exactly three minutes. If the conditions above stated are carefully followed, the volumetric percentage may be read off from the scale on the percentage tubes, and with it the corresponding gravimetric percentage and the corresponding number of grains of albumin to the fluid ounce will be indicated by referring to the table on the following page.

As already stated, the time required to carry out this test need not exceed fifteen minutes; and it has been ascertained from numerous observations in which the dried albumin was carefully weighed and compared with the table that the range of error by this method need not exceed one hundredth of one per cent. (0.01 per cent.) expressed gravimetrically. While such minimal errors are of no practical import, being in fact no greater than ordinarily claimed for the gravimetric method itself,⁶ nevertheless for the benefit of those who desire, so far as possible, absolute results, the chief sources of error and the best means of their avoidance will now be considered.

1. With regard to the urine, this should first be filtered and its chemical reaction ascertained, and if found to be neutral or alkaline it should be rendered frankly acid by the careful addition of a few drops of acetic acid, great excess being avoided. Next, if the quantity of albumin is excessive, as may be determined by a rough preliminary test, the urine should be diluted with one or more volumes of water until the volumetric percentage does not exceed ten or at most fifteen per cent. After a little practice quantities of albumin under fifteen per cent. will be obvious upon precipitation, so

⁶ See Hammarsten, first edition, p. 599.

that preliminary quantitative testing will not be required save in cases of great excess.

2. With regard to manipulation of the reagents, the two cubic centimetres of fifty per cent. acetic acid should be added to ten cubic centimetres of the urine, the latter being as nearly as practicable of normal acidity, having been thus rendered as previously directed. The importance of proper acidity of the urine before submitting it to the test depends upon the facts (a) that if the urine is neutral or alkaline, the two cubic centimetres of acetic acid may not be sufficient to secure precipitation of all the albumin present, and (b) if the acid is in excess, it tends to dissolve the albumin after its precipitation.

After the addition of the two cubic centimetres of

acetic acid the tubes should be inverted three or four times to insure complete mixture with the urine; then three cubic centimetres of one-to-ten solution of potassium ferrocyanide should be added, the tubes again inverted till well mingled, and then stood aside for ten minutes. Those who are familiar with the behavior of potassium-ferrocyanide solutions in the presence of albumin will recall the fact that precipitation is somewhat tardy as compared with that with most other albumin precipitants. One of the possible sources of error with this test depends upon the above-named fact, because precipitation seems to be much slower in some cases than in others, depending largely upon the varying degrees of acidity of the urine. Observations conducted in this laboratory have demonstrated that if the urine is allowed to stand for ten minutes after the reagents have been added, all the albumin is precipitated. It will also be recalled by those familiar with the ferrocyanide reaction that the latter rarely takes place with the proteids ordinarily found in the urine other than albumin, and therefore this reagent is especially suited for quantitative determinations of albumin. The quantity of albumin in the urine, when excessive, exercises a disturbing influence over all volumetric methods of measurement, it being practically impossible to secure uniform readings with small and large quantities of albumin indifferently. It has for this reason been found better to dilute the urine, in case the volume of albumin exceeds ten per cent., so that said volume shall range below ten per cent. It has been ascertained under the conditions specified for this test that under ten per cent. the results are uniform. If, then, for example, a preliminary test shows twenty per cent. of albumin to be present, the urine should be diluted with two volumes of water, and the product should be multiplied by three before using the table. Minute errors may arise from measurements in diluting the urine, but with due care these should be practically eliminated, especially if the dilutions are made with the burette.

3. Lastly, with regard to packing and measurement: The first and most important essential is an efficient centrifuge. The Purdy electric centrifuge possesses all the essentials for exact work, including carefully graduated percentage tubes, proper radius, and speed indicator to secure uniformly graded speed, and all observations upon which this test is founded were conducted with this instrument. If this is at hand, very few additional suggestions are necessary. If the above-named instrument is not obtainable, one must be employed that possesses certain essential features, or is capable of such modification as will include these essentials, as follows: (a) It will be necessary to have two percentage tubes carefully graduated in tenths of a cubic centimetre of capacity of fifteen cubic centimetres each. These tubes are more accurate if the last two or three centimetres of the tube are drawn out somewhat conically at their tips. (b) The arm of the cen-

trifuge should be so constructed or modified that its radius is exactly six inches and three quarters—that is to say, the linear distance from the centre of the axle to the tip of either tube must be just six inches and three quarters. (c) The motor must be capable of an even and sustained speed of fifteen hundred revolutions per minute, with the required radius, and carrying thirty cubic centimetres of urine. Some reliable method of gauging the exact speed of the motor must be employed. Any centrifuge that fulfills the above-named requirements will give accurate results as indicated by this method and the accompanying table.

It may be stated in conclusion that nearly all the experimental observations upon which this method and table are established have been worked out upon samples of albuminous urine obtained from cases of actual renal disease. The method followed has been that of first carefully obtaining the exact volumetric percentage of the albumin; its careful separation upon a dry filter of known weight; subsequent drying in an oven until it no longer loses weight; then ascertaining the exact gravimetric percentage and comparing this with the previously ascertained volumetric percentage. For the benefit of those who may desire to investigate this subject, but who may not have access to the necessary samples of albuminous urines, it may be stated that solutions of Merck's purified serum albumin in normal urines have given closely corresponding results in this laboratory with those obtained from albuminous urines in cases of renal disease.

Acknowledgment is due my assistant, Mr. Carl Irenaeus, for his efficient and tireless assistance in carrying out the almost endless details of the many observations necessary to the establishment of this method.

57 EAST TWENTIETH STREET, May 15, 1899.

A SEVERE CASE OF PUERPERAL SEPSIS TREATED BY ANTISTREPTOCOCCUS SERUM AND UNGUENTUM CREDÉ.

RECOVERY.

By JAMES D. VOORHEES, A. M., M. D.,

INSTRUCTOR OF OBSTETRICS AT THE COLLEGE OF PHYSICIANS AND SURGEONS,
RESIDENT PHYSICIAN OF THE SIOUX MATERNITY HOSPITAL.

A. McC., twenty-one years old, a primipara, was admitted to the hospital at 1:30 p. m., January 3, 1899, in the first stage of labor. The vertex was presenting, R. O. P., above the brim.

She had a fairly long first stage—twenty-one hours—and gave birth spontaneously to a child weighing seven pounds and eleven ounces.

The placenta was partially adherent and came away incompletely by expression. She was bleeding furiously. The patient had had a bad leucorrhœa during pregnancy, with symptoms of gonorrhœa, and there were small chancreoidal ulcerations just inside the vulva on the right side.

There were two indications to empty the uterus—retained secundines and hemorrhage. Yet there was

the danger of carrying infection from these ulcerations into the uterus. This risk was taken, and, after thoroughly emptying the organ and giving a hot douche, the bleeding stopped.

After delivery the patient's condition was not good. She was restless and pale, pulse 150. She responded, however, to stimulation, and the next morning was in fairly good shape, except for a tender fundus. On January 6th, her third day, there was some odor to the lochia and the temperature was 100.2° F. in the afternoon. She was ordered creolin douches for the vagina three times a day.

January 1th, at 2 A. M., the patient had a temperature of 102.8° F., and her pulse was 136. At 9:45 A. M. she had a severe chill, followed by a temperature of 103.2° F., pulse 160. She was then given chloroform and examined. There was a small abscess in the left vulvovaginal gland. Some excoriations of the vagina and tears of the cervix were covered by a black slough in some places and a yellow exudate in others. A foul discharge exuded from the os. The abscess was opened and cleaned. The vagina was douched. The uterus was thoroughly curetted, douched, and packed with iodoform gauze. Some foul debris had been removed. She was in very bad shape during the operation; the pulse was between 180 and 200. She was actively stimulated. This manipulation was followed by a severe chill and a temperature of 104.5° F.

On the next day, January 8th, the gauze was removed and the uterus douched every two hours with normal salt solution. Chills occurred on this day, and the following one also. Then intra-uterine douches every six hours were started. She was getting vigorous stimulation and nourishment was forced.

On January 11th, the eighth day, she showed phlebitis of the internal saphenous vein near the left knee.

On January 12th three small abscesses from hypodermic injection in the left gluteal region were opened and packed. She now seemed to improve till the thirteenth day, when the temperature dropped to normal, only to be followed by a severe chill.

Chills now started and occurred once or twice a day. She was getting pyæmic. But repeated examinations failed to find a localized suppurative process. The abscesses of the thigh were healed, the phlebitis was well, and there was very little discharge from the uterus and nothing palpable in the broad ligaments. The intra-uterine douching was therefore discontinued. Chills occurred just the same. She looked very badly, and death was expected at any time. The pulse after the chills rose to 160-170.

On January 23d, her twentieth day, a culture was taken from the uterus and examined by Dr. W. H. Park. No streptococci were found, but only a short bacillus, which seemed likely to be the colon bacillus. Blood taken from the right median basilic vein and planted by Dr. James Ewing gave no growth. Thinking that the infection might have been from the streptococci at the start, and the condition of the patient being so poor, we thought it wise to try the anti-streptococcus serum. That of the New York board of health was used. At 1 p. m., January 23d, ten cubic centimetres were injected into the back. The temperature fell to normal, and stayed so for six hours, when another chill occurred.

She was given ten cubic centimetres of serum twice a day till January 27th—nine injections altogether being used. There was no improvement, however. On this

day, her twenty-fourth day, she was still in very poor shape, yet we were surprised at her vitality. The physical examination showed nothing positive. Her lungs seemed normal; the heart's action was feeble, irregular, and intermittent; a systolic murmur was heard over the apex and the rest of the cardiac area. The liver and spleen were large. The abdomen was boggy distended. No tenderness. No masses were felt.

The uterus was astonishingly well involuted, not tender, freely movable, with very little discharge; otherwise the examination was negative.

Diagnosis.—Possibly malignant endocarditis. Hers was not considered a case for laparotomy—in fact, she could not stand such an operation.

Having read of the good results of silver salts in other kinds of infection, and also the remarkable case of puerperal sepsis of Dr. S. S. Jones, read before the New York Academy of Medicine, and published later in the *Medical Record*, February 11, 1899, we thought it worth while to make a trial of this treatment. At 2 P. M. a drachm of unguentum Credé was rubbed into the right groin. Another drachm was used at 10 P. M. The patient seemed to improve immediately. She had no further chills for three weeks. This treatment was continued thirty-four days. It did not effect a cure, for in this time the patient had a number of complications. On January 29th she had a pulmonary infarct of the left chest with considerable pleurisy, requiring morphine and strapping.

On February 10th the small joints of the hands and feet, the wrists, elbows, and shoulders, the ankles and knees were red, tender, and swollen—very painful on motion. There was a papular erythema of the extremities. Splints were applied and morphine was given for the pain. The next day the temporo-maxillary joint was involved. There were no chills nor was there any exacerbation of the temperature. The patient looked deathlike, and her recovery was given up. On February 15th, however, she was much better and the splints were removed. She looked astonishingly well and felt hungry. The temperature was much lower.

On February 17th, her forty-fifth day, the temperature was 102.6° F. in the rectum. Complete examination was negative, except for a large tender tumor in the right lumbar region. This was probably the kidney. Analysis showed the urine to be acid; specific gravity, 1.026; a trace of albumin; five per cent., of pus.

Chills followed for two days.

On February 20th the tumor was smaller and less tender; twenty per cent. of pus in the urine. The temperature now rose for a short period each day till March 4th. The rises were probably due to the retention of pus in the kidney, as the tumor was larger from time to time and there was an intermittent pyuria.

On March 1st the use of unguentum Credé was discontinued.

On March 8th she had her last rise in temperature, 102.8° F.; no pus. After this the kidney was not palpable, and there was very little pus in the urine. She was now gaining rapidly. She got up out of bed March 11th, and was discharged March 23d in first-class condition, eighty days post partum.

Diagnosis.—Puerperal sepsis, pyæmia, phlebitis, gluteal abscesses, pulmonary infarct, general arthritis, and suppurative nephritis.

Remarks.—1. It is to be regretted that no culture was taken either from the blood or from the uterus at

the onset, for certainly there were more virulent germs at work than the colon bacillus.

2. The recovery from such a protracted and severe pyæmia is remarkable.

3. The antistreptococcus serum did no good, nor did it accomplish any harm.

4. The improvement after the use of the inunctions of the silver ointment did not seem to be a coincidence; although it did not effect an absolute and immediate cure, as in Dr. Jones's case, it certainly turned the tide toward recovery. The general condition improved at once. The patient was hungry and more rational. The ointment did not prevent complications, but undoubtedly it fortified the patient and increased her resistance, so that she managed to survive them.

The chills, which had been occurring twice a day, stopped immediately and did not occur again for three weeks, and then they were due to the suppuration in the kidney. These chills were much less severe.

5. The ointment is not a remedy for all cases of sepsis. The preliminary curettement of the uterus, the frequent douching as long as the discharge is profuse and the uterus is not draining well, the forced feeding, and the vigorous stimulation must be used with good judgment at the beginning of the infection and during this method of treatment.

At the Sloane Maternity Hospital we have used the inunctions in one other case. This patient died. She had gangrenous metritis, so general that hysterectomy at the onset alone could have saved her.

6. There were sixty-eight inunctions in this case, a drachm each, Schering and Glatz's preparation of unguentum Credé. There was no depression, no albumin in the urine, no argyria, and there were no poisonous or bad symptoms from its use.

This case occurred in the service of Dr. E. B. Cragin, with whose kind permission I publish it.

447 WEST FIFTY-NINTH STREET.

THE USE OF HOLOCAINE AS A LOCAL ANÆSTHETIC IN EYE, EAR, NOSE, AND THROAT OPERATIONS.*

BY JOHN GUTTMANN, M. D.,

OCULIST AND SURGEON OF THE EAST SIDE DISPENSARY;
ASSISTANT SURGEON OF THE OPHTHALMIC AND AURAL INSTITUTE;
FELLOW OF THE ACADEMY OF MEDICINE OF THE CITY OF NEW YORK.

BEFORE entering upon my subject to-night I intend to dwell briefly upon the history of cocaine, a drug which up to the present time has been universally used as a local anæsthetic. In 1855, Gaedecke separated from coca leaves a crystalline alkaloid which he called erythroxyline. Five years later Mantegazza and Albert Nieman examined the alkaloid more thoroughly, and the latter named it cocaine. Nieman had at that time

* Read at the meeting of the German Medical Society of the City of New York, March 6, 1899.

already recognized the value of cocaine as a local anæsthetic on mucous membranes. Three years later Moreno y Maiz for the first time employed cocaine hypodermically, and that with very good results. For the following twenty years this very valuable drug was known to only very few persons, and no special attention was paid to it until 1884, when Koller* showed us in numerous publications of his experimental investigations its useful application in ophthalmology. Shortly after Koller, Jellinek,† also an adept of the *alma mater viennensis*, demonstrated the usefulness of cocaine in ear, nose, and throat operations. Those can best appreciate the great achievement of Koller and Jellinek who were formerly compelled to perform cataract extractions or iridectomies without the help of cocaine, and those who, like Tuerk, made their laryngeal examinations and operations with applications of a morphine solution, or, like Schroeter later, with a combination of chloroform and morphine solutions. No great imagination is needed to appreciate all the difficulties and dangers coupled with such a procedure. On this side of the ocean Dr. H. Knapp‡ was among the first who, as a result of his experiments on himself and on his patients, contributed most to the promulgation of its use. But a reaction shortly followed the great enthusiasm for the miraculous properties of cocaine. Numerous reports of unpleasant accidents, yes, even deaths, caused by cocaine came in from several sources. It is evident that a search for a substitute became general. But none of the drugs recommended, such as eucaine, anisine, etc., with the notable exception of holocaine, could be compared in efficacy with cocaine. It was three years ago that Dr. Tauber* discovered holocaine, a drug which promises not only to replace cocaine, but on many occasions to excel it.

I have used holocaine both in my private and dispensary practice since November, 1897. Before I employed it on my patients I tried it on myself and four other healthy persons. I instilled two drops of a one-per-cent. solution of holocaine into my left eye and two drops of a four-per-cent. solution of cocaine into my right eye. Soon a difference in the aspects of both eyes was apparent; whereas the holocainized eye was red and inflamed, the cocaineized eye appeared pale and anæmic. Both eyes became anæsthetic at about the same time. I could not verify the statement of Scherer|| that the onset of anesthesia is earlier in the holocainized eye than in the cocaineized eye. The other subjects of my experiments also gave such contradictory reports as to the rapidity of the onset of anesthesia that I became convinced that both drugs produce their anæsthetic effect in about the same time. In my investigation I found

that the cornea becomes anæsthetic first, then the scleral conjunctiva, and lastly the palpebral conjunctiva. Sensation in these structures returns in the reverse order. Both in me and in the majority of my subjects the duration of anesthesia was a little longer in the cocaineized eye than in the holocainized eye. This last observation stands again in contradiction to that of Scherer, who states that the anesthesia produced by holocaine lasts longer than that produced by cocaine. A further and more striking contrast was evident in the appearance of the two eyes in the following respects: Whereas in the holocainized eye the pupil, the tension of the bulbus oculi, and the fissure of the lids remained unchanged, in the cocaineized eye the bulbus appeared more protuberant and was softer, the pupil was dilated, and the aperture of the lids was considerably enlarged. To compare the effect of holocaine on the accommodation with that of cocaine, I brought the Jaeger test card alternately closer and closer to my eyes, until the letters of Jaeger No. 1 appeared dim and illegible. I found that I could bring the test card fully half an inch to an inch nearer to the holocainized eye than to the cocaineized eye. In the eyes of the younger subjects there was a difference in the distance of approximation of the test card to both eyes of an inch to an inch and a half. When a convex glass of 1 D. was placed alternately in front of each eye, I could read with the cocaineized eye $\frac{2}{3}$ %, and with the holocainized eye $\frac{2}{3}$ %. With the same lens the younger subjects could read with the cocaineized eye $\frac{2}{3}$ %, with the holocainized eye $\frac{2}{3}$ %. After that I had one of my nostrils anesthetized with cocaine and the other with holocaine. The anesthesia set in with me, as well as the other subjects on whom I made the same experiment, generally in five to seven minutes sooner in the cocaineized than in the holocainized nostril. By touching the dorsum of my tongue, the pharynx, and the larynx with cocaine, I felt a bitter metallic taste. There was a sense of choking and of strangulation in my throat. But an application of holocaine to the same structures produced neither such an intensely bitter taste nor any of the other disagreeable sensations.

After this experience I used holocaine on my patients. I soon had an opportunity of using holocaine on a patient with a nasal spur on both sides which obstructed his nasal breathing. I sawed off one spur under holocaine anesthesia, and the other, a few days later, under cocaine anesthesia. The intensity of the anesthesia was the same on both sides, but it manifested itself in the cocaineized nostril eight minutes after the application, while in the holocainized nostril only after fifteen minutes. And, whereas after the use of cocaine the patient experienced a very unpleasant bitter and metallic taste, he was not troubled with these sensations when I used holocaine. We began in the cocaineized nostril to treat a polypoid growth, which was pale and contracted, so that the nasal passage became entirely

|| *Kansas City Med. Index*, 1898.

free, in the holocainized nostril the swelling of the turbinated bodies did not diminish. Both during and after the operation the hæmorrhage in the cocaineized nostril was very slight, but in the holocainized side it was quite considerable. After this I had the opportunity of using at one time cocaine and at another holocaine on a patient suffering from phthisis laryngis, for the purpose of mitigating his dysphagia. The patient was always better satisfied when I used the new remedy, holocaine, for it did not cause an unpleasant bitter, metallic taste in his throat. Afterward I used holocaine in a cataract extraction, in a dissection of a secondary cataract, in tenotomies for strabismus, and in squeezing of granular trachoma. I used it in the removal of tumors of the eyelids, of foreign bodies from the cornea, of granulations and polypi from the middle ear, of nasal polypi, and of hypertrophies of the turbinated bodies; also for the performance of tonsillotomy, for the removal of adenoid vegetations, of laryngeal polypi, etc., always with very good results. I also assisted Dr. H. Knapp in a large number of operations in which holocaine was used instead of cocaine with perfectly satisfactory results.

According to Traube's researches, the chemical nature of holocaine is as follows: Holocaine is a derivative of *p*-phenetidine, and is in close relation to lactophenine and phenacetine. The chemical name of the latter is acetyl-*p*-phenetidine. Holocaine is to be considered as formed by the union of molecular amounts of phenacetine with *p*. phenetidine and the elimination of water, according to the formula:

According to Schlosser,* the product of this union is a beautiful crystalline, strong base, which is insoluble in water and melts at 121° C. The chloride of the substance—which is holocaine—crystallizes in white needles, which are easily soluble in hot water. The saturated solution, which contains only 2.5 per cent. holocaine, is slightly bitter, neutral in reaction, and is not changed by boiling. When in making a solution of holocaine we boil the water in a glass vessel, or if we pour a hot solution of holocaine into a glass vessel, the solution becomes turbid, and the walls of the vessel become hazy and opaque. This turbidity is caused by the fact that the boiling water liberates some of the alkali of the glass, which, in turn, liberates from the solution some of the otherwise insoluble amidine base which constitutes the amorphous sediment. If we wish to avoid the cloudiness, we must use porcelain instead of glass vessels, or, according to Nathan-on,† to use glass vessels which have been previously boiled with muriatic water.

Physiology. According to Heintz,‡ the anæsthetic

effect of holocaine is produced by a paralysis of the terminal sensory nerve fibres, and not secondarily by ischaemia or frigidity, as is the case with some of the other local anæsthetics. He proved this by the following experiment: Having decapitated a frog and cut out its heart, he suspended the frog from a framework so that one of its hind extremities dipped into a one-third-per-cent. solution of HCl; in from two to three seconds after the immersion the leg was suddenly and violently jerked out of the solution. He then bathed the frog's leg in a one-per-cent. solution of holocaine, dried it, then bathed it in a 0.6-per-cent. salt solution, and then again immersed the leg in the one-third-per-cent. HCl; this time the frog's leg was not jerked out of the solution until five to twelve seconds after the immersion. He found that the longer he bathed the extremity in the holocaine solution the longer was the reaction period; that if the immersion lasted one minute, the leg was not withdrawn from the HCl solution at all. Thus he demonstrated that holocaine acts by paralyzing the terminal filaments of the sensory nerves. A one-per-cent. solution of holocaine retards the growth of bacteria, and it is therefore a good antiseptic. When brought into the circulation, holocaine proves to be a powerful convulsive poison, similar to strychnine. The toxic dose of holocaine for mice is 0.001 gramme; for rabbits of two thousand grammes, 0.01 gramme (of cocaine, 0.05 gramme; of eucaine, 0.075 gramme).

In a discussion as to the relative merits of local anæsthetics, eucaine, as compared with cocaine and holocaine, may be left entirely out of consideration, inasmuch as it not only has no advantages over these remedies, but has positive disadvantages. As regards holocaine and cocaine, the results of my investigations on healthy eyes may be briefly summarized as follows: Both cocaine and holocaine possess the common property of paralyzing the terminal filaments of the sensory nerves, and both are therefore good local anæsthetics. For practical purposes there is no great difference between them, as regards the time of onset or the duration of anæsthesia. Nor do they materially differ in the intensity of the resulting anæsthesia. Either remedy may therefore be used indifferently in the ordinary operations on the eye. But whereas the cocaineized eye in my experiment was pale, protruding, of lowered tension, with the pupil dilated and the fissure of the eyelid enlarged, the holocainized eye was red and inflamed, of normal tension, not protruding, pupil normal, and palpebral fissure not enlarged. This difference in the effects of cocaine and holocaine is explained by the well-known action of cocaine as an irritant to the terminal sympathetic nerve fibres, and its consequent vasoconstrictor effects. The pallor of the eyeball is therefore due to the powerful contraction of the blood and lymph vessels following the application of cocaine. The haziness and dryness of the cornea are also due to the vasoconstrictor effect of the cocaine, although the abolition of the reflex

* *Klin. Monatsbl. f. Augenhe.*, 1897.

† *St. Petersburg and Wochenschrift*, 1897.

‡ *Klin. Monatsbl. f. Augenhe.*, 1897.

nictitatory functions of the eyelids, as a result of the anæsthetic condition of the eye, is also partially responsible for them. But neither in my observations nor in the experiments of others was any effect of holocaine on the sympathetic nerves to be observed. From these observations we may derive conclusions as to the indications for the use of either one drug or the other. For the removal of a foreign body from the cornea holocaine is to be preferred, for, unlike cocaine, it does not produce the subsequent disagreeable mydriasis; also for a strabismus operation is holocaine to be preferred, for cocaine causes the muscle to shrink, and thus often permits some muscular fibres to escape the strabismus hook. In the treatment of inflammatory affections of the conjunctiva and cornea, associated with painful blepharospasm, holocaine is of great value, for it not only relieves the spasm and allays the pain, but also acts as an antiseptic, and thus as a curative agent. But, on the other hand, cocaine is to be preferred in the performance of an iridectomy where the arteries appear atheromatous and where we would avoid a considerable hæmorrhage. The vasoconstrictor effect of cocaine, and the diminished tension of the eyeball, together with the subsequent deepening of the anterior chamber, are all factors in favor of using cocaine for the performance of an iridectomy under these circumstances. For the extraction of a cataract where the pupil is small, cocaine is to be preferred on account of its mydriatic action. For the many other operations on and about the eye, these two agents may be used indifferently, unless, indeed, the bactericidal action of holocaine should incline us to use it in preference to cocaine. This latter consideration is sometimes of great importance, especially if we consider the time and trouble it requires to sterilize a solution of cocaine. In choosing our anæsthetic for operations on the ear, nose, and throat, we must consider whether the disadvantage of the freer hæmorrhage following the use of holocaine is more objectionable than the disadvantageous and undesirable shrinkage of the tissues following the use of cocaine. That the shrinkage of the tissues caused by cocaine is at times a disadvantage is illustrated by the following case: A lady of a somewhat nervous disposition, suffering from obstructed nasal breathing, was recommended to me by Dr. L. for treatment. On examination I found an hypertrophy of the posterior tip of the inferior turbinated body. The lady being very sensitive, I applied some cocaine solution to the nostril in which I intended to operate; but on introducing the cold snare, I found that the tumor, which was previously so evident, could not now be seized with the instrument. A second examination showed me that the reason for this was the almost complete shrinkage of the tumor caused by the cocaine. Had holocaine been my anæsthetic, I should have been spared the vexation of having to ask the lady for a second visit for the performance of the operation. Besides the well-known bitter taste and disagreeable choking sensation which co-

caine produces when applied to the nose and throat, it also produces a sensation of dryness which causes the patient to hawk so much that very often profuse hæmorrhage results. All these undesirable phenomena are entirely absent when we employ holocaine. Obviously, then, holocaine is to be preferred to cocaine, not only when we wish to avoid the shrinking effect of cocaine, as in the removal of granulations from the ear, of hypertrophies of parts of the turbinated bodies, of small polypi in the ear, throat, or nose, etc., but also when we wish to avoid the other disagreeable effects of cocaine when operating on the aforesaid organs. It must be evident to all that holocaine is a valuable substitute for cocaine in persons who have unfortunately become victims of the cocaine habit, and in those exposed to the same danger from the frequent use of cocaine for the amelioration of some complaint. In conclusion, I wish to say that during the last year I have employed holocaine instead of cocaine in about a hundred and fifty operations, and have never observed the slightest toxic or alarming manifestation. According to the investigations of several writers, it is not advisable to use holocaine hypodermically. Although holocaine will never entirely replace cocaine, yet it will frequently be of equal service, and, under certain circumstances, will even be preferred to it.

709 MADISON AVENUE AND 358 EAST FOURTH STREET.

ON A COMPOUND MICROSCOPE FOR VIEWING THE EYE.

By LUCIEN HOWE, M. D.,

CHICAGO.

As instruments of precision of any real value are always welcome to the ophthalmologist, it seems worth while to call attention to a form of the compound microscope which gives a decidedly better view of the anterior portion of the eye than any similar instrument. I am aware that the compound microscope has already been arranged to view the eye, and I think it was at one of the meetings of the Ophthalmologische Gesellschaft in Heidelberg that I first saw the instrument, but the view given by that microscope was by no means so clear or well magnified as that obtained by the one here referred to. The excellence of this instrument should in fairness be credited to Mr. Henry L. de Zeng, Jr., of this city, and if a name were given to it, it might be called a keratomicroscope, that being a little more convenient than to speak each time of "the large horizontal microscope arranged for viewing the anterior portion of the eye."

The accompanying illustration shows the arrangement of this microscope and indicates at a glance its use. The following are approximately its measurements: The objective consists of two systems. The front or distal lens has a diameter (clear aperture) of

3.2 centimetres, the proximate lens a diameter of 5.1 centimetres, and they are separated from each other about eight centimetres. The two systems combine to give a focal distance of about twelve centimetres and an angle of aperture of thirty-five degrees. This system is connected with the eyepiece by a tube 25.5 centimetres long and twenty-one centimetres in circumference. Into this outer tube there is fitted a draw tube. There are two eyepieces. One has a focal length of about nine centimetres, and gives a minimum amplification of twenty diameters to a maximum of about fifty, according to the position of the draw tube. The other eyepiece has a focus of 2.5 centimetres, giving a minimum amplification of fifty diameters or a maximum of about one hundred and twenty-five, also according to the position of the draw tube.

The microscope is mounted horizontally on a firm tripod attached to an upright bar. As this bar can be lengthened or shortened, the microscope can be lowered or raised, and it swings horizontally on the axes of the bar. There is a hinge joint allowing the elevation or depression of the tube at any angle, and by means of a rack-and-pinion adjustment it can be pushed forward or backward. In a word, the microscope can at once be brought into any position desired.

When making an examination, the patient faces the instrument, the eye being approximately near the focus of the objective. The results are better if the chin is placed on a head rest, such as is provided for the perimeter, or, still better, if the whole head is also steadied by such a head rest as was suggested by Stevens for his "tropometer." The results are also more satisfactory if the illumination is good. Ordinary daylight is sufficient for most purposes, but, if specially good views are desired, these can be obtained by bringing a shaded electric light within a foot or two of the patient's head, or by allowing the light coming through a double-con-

vex lens to fall obliquely on the eye. While these details are given concerning the most desirable position of the patient and the degree of illumination, it should be borne in mind that such care is by no means essential.

The patient having been seated, the head adjusted, and the light arranged, the objective is brought within a few inches of the eye, and almost immediately the direction and the focus are easily obtained. The view presented is quite striking to one who for the first time uses a microscope in this way, though with the ordinary pocket lens we are accustomed to see one somewhat similar to it every day.

The advantages of this compound microscope over the pocket lens, or over any other compound microscope constructed for this purpose, are: First, in the degree of amplification. This is far beyond that possible to the pocket lens, unless, of course, for the small point, more or less imperfectly defined, which is immediately at the focus. Second, in the clearness of definition. The careful correction of spherical and chromatic aberration gives us a view of the outer portion of the eye which is remarkable for distinctness and beauty. Third, in the size of the field, as indicated by the angle of aperture already described. With low magnification the entire cornea and iris are easily visible, except the segment usually covered by the upper lid, and even when the amplification is greater the field is proportionately large.

As to the real value of the instrument, I would say, first, it is probably of some use in observing physiological variations in the size and form of the pupil.

As to this point, it would seem almost impossible to obtain any new data after the careful studies made by Leber, Aubert, and other investigators. I must confess, however, that before using the microscope in this way, I never appreciated the almost perpetual motion visible in the normal iris when moderately contracted. Thus, if the pupil be illuminated only from the side with a moderate light, the rest of the room being partly darkened, it is easy to count fifteen, eighteen, to twenty or more distinct contractions, with corresponding dilations, within thirty seconds. By simple experiments it is easy to determine that many of these contractions are due, as we should expect, to efforts at accommodation; but whether others are due to variations in the blood current, or perhaps indirectly to mental processes, it is difficult to ascertain. It would form an interesting field for investigation.

Not only are the variations in the size of the pupil more easily seen than with the naked eye, but in certain cases it is interesting to notice the changes in form. Eversbusch long ago called attention to the fact that the human iris occasionally tends to resemble in structure that of the carnivora—namely, that there is sometimes a distinct interlacing of the sphincter fibres above and below. This tendency to the oval form I have noticed with the microscope when a mydriatic is commencing to have its effect.

Second. A microscope thus mounted is of assistance in studying certain pathological conditions. Among these I would specially mention:

(a) Small opacities on the cornea—although for this, or for detecting foreign bodies, the instrument is not as useful as might be expected, and infinitely less convenient than the pocket lens.

(b) The extent or changes in ulcerative processes in the cornea. The edges of an ulcer, its depth, and the character of the deposit, can not only be seen better than with the pocket lens, but, when the reparative process begins, the flatness of the field shows very beautifully the loops of fine capillaries which advance from the corneal margin, changing sometimes from day to day.

(c) Edema of the iris, circumscribed or general, with or without exudation, can be seen readily. The crypts are either partly filled or obliterated with deposit, the trabeculae in the lesser circle become indistinct, and the circular contraction grooves near the peripheral margin show beautifully the effects of the swelling. By observing these at intervals it is possible to notice changes in the iris which, as a whole, ordinarily escape detection.

(d) It is interesting to contrast the normal active pupil with one torpid or paralyzed. Our ordinary methods of testing the pupillary reaction are certainly inaccurate, and if, as it appears, we have in the compound microscope, thus arranged, an instrument for recognizing imperfect motion of the iris, it will probably give an indication as to incipient diseases of the optic nerve, assist in the differential diagnosis of a toxic or hysterical amblyopia, and in the detection of simulated blindness.

Third. The microscope is certainly of value in photographing the anterior portion of the eye, in either a normal or an abnormal condition. Any one who has attempted work in this direction will appreciate the advantage of having sufficient amplification with a clear, flat field. With this microscope a photograph has been taken of the iris more than twenty-five centimetres in diameter.

In referring to this microscope and the work which it will do, I have endeavored to be rather moderate in the statements, remembering that in the description of any instrument one is apt to magnify its virtues even more in proportion than the instrument will magnify its object. Apparently, however, it is sufficiently useful not to be consigned to the limbo of discarded scientific toys, but to be of some real value to the working ophthalmologist.

Dr. Osler the Cavendish Lecturer.—The Cavendish Lecture of the West London Medical-Chirurgical Society on Cerebro-spinal Fever was, we learn from the *British Medical Journal* for June 3d, to be delivered on June 16th at the town hall, Hammersmith, London, by Dr. William Osler, F.R.S., of Johns Hopkins University.

THE STATE OF THE GASTRIC SECRETIONS IN ORGANIC DISEASE OF THE HEART.*

By FRANK H. MURDOCH, M.D.,

PITTSBURGH, PA.

DURING the last few years I have examined the gastric contents of twenty-three persons with organic heart disease. Hüller was of the opinion that free HCl was absent in almost all cases of valvular heart lesions, but subsequent examinations made by other observers have shown that this is not the case. For example, Einhorn, in twelve cases examined, found that free HCl was present in eight and absent in four. Adler and Stern, in twenty cases examined, found free HCl always present in sixteen, variable in two, and always absent in two cases. Hemmeter found the gastric secretions normal in eight cases of mitral regurgitation, two of aortic regurgitation, and two of mitral insufficiency.

In my own cases an aortic systolic murmur was present in five. Free HCl was present in four of these cases and absent in one.

A mitral systolic murmur was found in eight cases. Free HCl was absent in one case, subnormal in one, and nearly normal in the others.

A mitral presystolic murmur was found in five cases. Free HCl was absent in one case, normal in one, and in excess in the other three.

An aortic and mitral systolic murmur was present in four cases. In one, free HCl was present in excess, and absent in the others. Of the three cases in which HCl was present, in one the total acidity was ten, and rennet was absent. In the two others rennet was present; the total acidity in one was twenty, and in the other seventy-two.

Simple hypertrophy of the left ventricle, due to prolonged muscular exertion, was present in one case. HCl was absent, rennet was present, and the total acidity was four.

It will be seen, therefore, from the record of these sixty-seven cases, that there is no constant relation between the state of the gastric secretions and any one form of organic heart disease. Neither does the presence of heart disease seem in many cases to stand in the way of the recovery of patients suffering from the various forms of stomach trouble, for my records show that such patients get along just as well on the way to recovery as those whose hearts are in a normal condition.

Of the twenty-three patients examined, three came in only a few times, ten were seen but once, three were greatly improved, and seven made complete recoveries.

In those who recovered or were greatly improved, intra-gastric fermentation was noted in seven, lavage and faradization in one, and lavage alone in two. The patients were directed to abstain from bathing, exercise, etc., and the diet was in each case carefully regulated.

* Read by title at the annual meeting of the American Gastro-Enterological Association, Washington, D.C., May 18, 1899.

Therapeutical Notes.

Uropherine as a Diuretic for Children.—Dr. A. Schmid (*Klinisch-therapeutische Wochenschrift*, 1898, No. 43; *Monatsberichte über die Gesamtleistungen auf dem Gebiete der Krankheiten des Harn- und Sexual-Apparates*, iv, 4, 1899) has found uropherine salicylate quite as effective as the more expensive diuretin. He gives the following formula:

R Uropherine salicylate . . . 75 grains;
 Water 1,800 "
 Vanillin $\frac{1\frac{1}{2}}{100}$ of a grain;
 Mucilage of acacia, } each, 825 grains.
 Syrup, }

M. A teaspoonful three or four times a day. The benzoate of uropherine may be used if there is an idiosyncrasy for salicylic acid.

Sugar in Dermatology.—Hodard (*Semaine médicale*, 21, 1899; *Gazzetta degli ospedali e delle cliniche*, May 18th) has found great service from the siccativ and keratoplastic properties of powdered sugar when added to various unguents for use in moist eczema, impetigo, ecthyma, and other vesicular and pustular dermatoses. The author uses the following formula:

R Lanolin,
 Vaseline,
 Powdered sugar, } of each . . . 300 grains;
 Oxide of zinc,
 Glycerin, }
 Sulphur, } of each 150 "

M.

For Cystitis.—Ribiero (*Dunghlison's College and Clinical Record*, April 15th) recommends:

R Salol 150 grains;
 Salipyrine, } of each, 75 "
 Bromide of camphor, }

M.

Divide into twenty capsules. One to be taken every three hours.

Also: Benzoic lemonade made in concentrated decoction of *uva ursi* (bearberry) and hordeum (barley). Four to six tablespoonfuls daily.

For Epididymitis.—The *Riforma medica* for May 4th ascribes the following to Neumann:

R Extract of belladonna 15 grains;
 Simple ointment 300 "

M.

For local application.

The Treatment of Granular Conjunctivitis.—The *Riforma medica* for May 8th attributes the following to Bloebaum:

R Sulphate of copper, }
 Salicylic acid, } of each . . 1½ grain;
 Cocaine,
 Vaseline 150 grains.

M.

Anoint the conjunctiva therewith.

For Bronchorrhœa.—Maragliano (*Riforma medica*, May 15th) recommends:

R Benzoic acid 30 grains;
 Tannin 15 "

M. Divide into five powders. One to be taken every two hours.

THE NEW YORK MEDICAL JOURNAL.

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JUNE 17, 1899.

THE SIGN OF THE TONGUE IN INFLUENZA.

In the *Journal de médecine interne* for May 1st D'Hotel quotes the Arab proverb, "Death enters by the mouth," and asks, "May not the same formula be true of influenza?"

The author's attention was directed some time since to a special form of angina which with general febrile disturbance he found to precede by a period of from three to five days the gastro-intestinal and thoracic complications, which, as a rule, are only secondarily developed in influenza. He therefore set to work to investigate whether these prodromes of pharyngitis and stomatitis noticed by him had been general, or were merely a local manifestation of the epidemic. In the course of his investigations he found that alongside of the before-mentioned symptoms, which appeared inconstant, there was uniformly present in both slight and grave cases a condition of the tongue so peculiar and characteristic as to be almost pathognomonic.

This condition consisted in the formation, on the next day or the next day but one after the invasion, of a white, opalescent coating, more or less thick, and covering the centre of the tongue. Subsequently, according as the attack was light and cut short, or became prolonged and complicated, the coating diminished, beginning from the tip, or remained. This sign was the last to disappear; and according to the author it was not rare to find, three weeks after the invasion, a whitish triangle still at the base of the tongue, bearing testimony to its previous condition, and indicating that the patient was yet in a latent morbid condition, however much his functional condition might appear to have returned to normal; a condition in which any imprudence, a chill, etc., might light up a broncho-pneumonia or other complication.

But the most important character of this sign was its chemical reaction. Not only was it very persistent, in spite of laxatives and intestinal antiseptics, but, while the reaction of the buccal fluid normally gives a neutral or only very faintly acid reaction, as soon as the fur appeared the test paper reddened strongly, especially when rubbed against the fur. This acid reaction diminished as the disease abated, in ordinary

cases beginning to weaken from the sixth or seventh day. When the reaction returned to normal, however, if there was the least patch of fur remaining on the tongue, the litmus would still redden strongly on being rubbed against it.

From these facts the author naturally reasoned to an alkaline treatment of influenza, and according to his experience that has proved of the greatest possible value. The frequent administration of alkalis in sufficient doses, while they had little effect locally upon the tongue, merely cleansing it without removing the coating, he found to produce a lessened duration of the disease, a more free and prompt restoration to health, and a much greater infrequency of complications. Even when complications were already declared, this treatment appeared to be markedly beneficial, more especially in thoracic complications of all kinds.

It seems to us that the accuracy or otherwise of the author's observations should be easily established, the correctness of the reaction test being especially amenable to general investigation; while the course of treatment suggested by him, being a rational deduction if his premises are sound, can with equal ease be put to a practical test for verification. The investigation is one which can be carried out without effort by the vast mass of general practitioners, who, as it happens, have the largest practical acquaintance with the disease.

THE RIGHT OF WAY FOR THE INFIRM.

THE danger incurred by pedestrians in crossing the crowded thoroughfares of New York is growing greater and greater almost day by day. It is moderated to a certain degree during the summer months, when the carriages of the fashionable people are withdrawn for a time, and when traffic is not quite so brisk as it is during the trade season, but it is sure to be renewed and to be worse than ever by October. It seems to be too late to correct the asinine plan on which that portion of the town that lies between Washington Square and Central Park was laid out, whereby were provided plenty of cross-streets for travel over the short distances from the East River to the North River, while the streets running lengthwise of Manhattan Island were made few and far between, although the least approach to foresight ought to have shown that it was by them alone that the great preponderance of travel would have to be effected. As a general rule, the law seems to regard him who is traveling by the least manageable means of locomotion as entitled to the right of way. Now, a pedestrian's own legs are regarded as more thoroughly under his control than horses or any other form of traction power, hence,

but for certain restrictions as to the speed of vehicles, the pedestrian is expected to take care of himself. This he can generally do if he is an able-bodied man and not under the influence of liquor, although even such a person finds it very difficult at times.

The result of all this is that motormen, drivers of horses, bicyclists, and all who are not on foot insist that pedestrians must keep out of their way. There would be some excuse for this stand if all pedestrians were in possession of an active young man's powers, but no discrimination is made in favor of those who are handicapped with physical disabilities, persons infirm from age or other causes, and infants that have to be intrusted to nurse maids. It is no more than just to say that for the most part drivers of vehicles show special consideration for pedestrians who are obviously infirm. But this is not enough: there are thousands of men and women in the borough of Manhattan who betray no infirmity to the cursory observer, but, for all that, are the subjects of some disability which makes it highly dangerous for them to venture upon any attempt at agility. It may be that their disability interferes seriously with their perceiving in what direction they ought to dodge in order to escape being run down. Possibly it is nothing more serious than the epiphora which afflicts many a person yet in the prime of life on exposure to a cold wind. Fancy such a person trying to make his way home from his place of business between five and six o'clock of a stormy winter afternoon! The sidewalks and the crossings may be slippery or slushy. One hand is overtaken with the management of an umbrella that persists in playing the weathercock; the other hand is constantly on the alert to keep the man's hat on his head, vigorously sopping the watery eyes with the handkerchief ever and anon, to enable them to perform their function to some feeble degree under the blinding glare of the arc lights. When he comes to a crossing, he has to glance rapidly in four different directions, avoid mounds of ice and puddles, manage his hat and umbrella, and keep out of the way of a never-ending procession of trucks, cabs, cars, etc. He has to struggle with a difficult and dangerous task; yet, there is nothing about his general appearance to commend him to any tenderer consideration than is accorded to the most agile boy.

We believe this unnecessary peril to life and limb can be done away with in great measure. Certainly some attempt at doing away with it ought to be made. It seems to us quite right and feasible that some competent authority, the board of health, for example, should be empowered to issue to infirm persons some small and readily portable object—perhaps a red cross—made of

wood—the display of which should serve to warn the drivers of vehicles that the bearer had the legal right of way. Of course, such a device would have to be accompanied by a license, to be shown on demand as evidence that the person was not fraudulently profiting by somebody else's infirmity—in short, to bear the same relation to the emblem that a dog license bears to the tag on the animal's collar. We would have the emblem and the license obtainable only on satisfactory medical evidence of the existence of real disability, and we would have the holder's right of way made as unquestionable as that of a mail wagon, a fire engine, or an ambulance wagon.

THE BIOLOGICAL BASIS OF SEXUAL ETHICS.

The *Maryland Medical Journal* for May 13th, in an editorial referring to the annual recrudescence of sexual assaults by negroes upon white women, which occurs, it would appear, chiefly in the months of May and June, says that the anatomical and physiological conditions of the African must be understood, his place in the anthropological scale realized, and his biological basis accepted as being unchangeable by man before we shall be able to govern his natural uncontrollable sexual passions. When education and religious teachings change the biological basis of his color, they will also be able to change the physiological reason for his annual outbreak of sexual madness. To ignore the negro's inherent and peculiar sexual organization, it says, is to court failure; to accept boldly, frankly, and scientifically his ancestral traits, and to control him accordingly, it asserts to be the only rational, safe, and moral treatment of the negro question. This reasoning appears to us to be perfectly sound, but it is only part of a very wide subject; for the ignorance and willful overlooking of the overmastering influence of Nature in temperament, whether racial or individual, is so widespread that we believe a large part of the sexual irregularities occurring habitually among white races also must be attributed to the persistent exclusion of a biological basis from our codes of ethics or morals.

The normal state of man is one of absolute individuality. But when man emerges from an isolated existence and congregates in masses, it is obvious that the sovereign liberty of the individual must be at least so far limited that no one, in exercising it, shall be permitted to invade the liberty and equal rights of another. In the natural struggle to effect this end have been evolved morals or ethics—for the two are identical in strict meaning, whatever distinction conventionality may have erected between them—but to be effective

such morals or ethics must rest upon a biological basis, with due regard to circumstances and surroundings. The morals, ethics, or customs which different races of men, inhabiting widely removed countries and existing under widely diverse physical, climatic, and social environments, have evolved, necessarily differ in themselves very widely. Evolution is a slow process, and, as a race learns to survive by its aptness in adjusting itself to its environment, hereditary instincts grow stronger and stronger, until they become themselves Nature, and as hard to divert in another direction as they were hard to be arrived at in the first instance.

It is the smallness of grasp, the narrowed field of observation, that is responsible for most of the dogmatic theories that sway people's minds in varying directions when dealing with subjects such as this. What idea of the liver would a man attain to who, never having seen the organ as a whole or in macroscopical section, nor having even examined it microscopically under a low power, were to theorize concerning it from the laborious study of a microscopical section under a sixteenth-inch oil immersion lens? In nearly all controversies of this nature the rock upon which all parties split is the confinement of their view to microscopical sections, whereby they lose that sense of proportion and harmony which is only to be gained by beginning with the general inspection and proceeding by degrees to a more and more minute and detailed investigation.

If ethics is regarded in its proper sense as conformity with the normal in natural laws, then biology is the first consideration in the study thereof, the animal world the next, then the mammalia, and finally man, his races, their respective divisions and subdivisions, each and all carefully considered in relation to their circumstances and surroundings and impelling forces of every kind.

We do not ignore differences of racial or individual constitution in dealing with questions of food, sleep, or other physical needs; and, surely, to ignore the essential racial or individual differences in the sexual instincts when trying to control them for the benefit of the community at large is illogical, and, as it seems to us, can be only mischievous, whether in respect of different races or of different individuals of one race.

We do not mean to assert for one moment that these considerations should lead us to forego punishment in this any more than in other questions of breaches of law which endanger the public welfare, but that in dealing with and legislating for the prevention of such offenses due regard should be had to those inherent factors which are in constant operation, and that for such legislation to prove effective it must be in accordance therewith. We do not legislate for the proper control

and safeguard of explosives without taking into consideration the peculiar nature and conditions of their several explosive properties.

THE WASTE-PAPER NUISANCE.

THE extreme cheapness of paper, caused by the use of wood pulp in its manufacture, and its practical valuelessness after having served its original purpose, are very much in evidence in some sections of our large cities, particularly in the suburbs and wherever there is a vacant lot. It is blown about by every gust of wind, and collects under stoops and in fence corners, where it is sometimes set afire by mischievous or thoughtless urchins, to the peril of neighboring property. In some parks and groves resorted to by "basket parties" it also accumulates to such an extent as to rival the fallen leaves of autumn, but, unlike them, to be a positive eyesore. It seems to be as ubiquitous and uncontrollable as the English sparrow. It is untidy and dirty, and may under some circumstances act as a disseminator of disease. No effectual remedy for this evil has hitherto been devised, but we shall suggest a plan that, if adopted, might mitigate it to some extent. We propose the making of large grated iron urns, swinging on trunnions, into which papers could be put and burned. They could be made ornamental, and have a metallic label reading, "Burn papers herein," or something to that effect. The object of having them swing on trunnions is to empty them of stones or other incombustible matter that might get into them. If they were placed in picnic grounds, the children would see that all papers were consumed. They might even be put in suburban streets in proper places. In this case they should be heavy and firmly secured, to prevent their easy destruction or removal. All children like to play with fire; give them a safe, interesting, and useful way of gratifying their inclinations in this line, and they will hunt for the materials. Some police supervision is, of course, implied.

A PECULIAR MODE OF MASTURBATION.

DR. LOUISE DROUILLARD (*Woman's Medical Journal*, June) relates the case of a young woman of twenty-two, of bad family antecedents, who had been attacked with psychopathic symptoms coincident with menstrual derangement, and for some time had been in an asylum. When seen by Dr. Drouillard, the patient manifested choreic movements of the hands, sometimes of one hand, at other times of both, terminating by curious manipulations of portions of the face. The dorsum of the thumb was placed in the centre of the cheek, then with the middle finger pressure was made alternately on the tip of the nose and the tragus of the ear. After manipulating a few times in this way, the patient "would fold her hand in her lap with a far away pensive expression on her face, lasting some five minutes." A thorough investigation elicited the fact that the patient could produce sexual excitement and satisfaction by the manipulations before referred to. She did not seem to have any idea of wrongdoing, but was ashamed and distressed when the nature of her act was explained to her. This case calls attention to a possible explanation of many otherwise baffling psy-

chic on the part of young children, and should keep the practitioner ever on his guard in anomalous cases for possibly hitherto unsuspected methods of inducing sexual erethism.

PETROLEUM DRINKING.

THERE seems to be no limit to the extent to which people will go in their efforts to "steal away their brains" for a time. Not only alcohol in its various palatable forms, but even the methylated alcohol used for lamps, ether, sal volatile, and other things are used to produce that condition of inebriety whose chief charm would appear to be the banishment of all objectivity and the induction of a state "the world forgetting, by the world forgot," though occasionally the latter part of the formula is far from being attained. In Paris it would seem that there is danger of petroleum drinking becoming a craze. One would think the stuff was too nauseous to tempt any one's appetite. It seems that the chief advantage is supposed to lie in the fact that, while the subjective stage of inebriety is induced, it leaves no headache in the morning or other depressing feeling. Whether it has any ultimate injurious effects it is, of course, at present too early in the history of the vice to say; but whether it does or not, it is an evidence of the great craving for the production of an abnormal state, in which the objective relations are dulled and deadened, and the individual is, as it were, thrown back on his own subjectivity, with senses, feelings, and emotions dulled and energies rendered compulsorily quiet.

The inebriety that comes from wines is a natural process, in this sense that it is usually the taste that first attracts, and the systemic effects that are found to be pleasurable follow subsequently. But in this new vice it must be a deliberate seeking after the abnormal deadened condition that prompts to it. We fancy that many of the excesses that are common are the inevitable result of centralization and overcrowding of masses together in cities, and the increasing struggle thereby rendered necessary to provide for artificially aroused cravings. The truest movement toward temperance would, in our opinion, be a movement from the towns and artificial conventional life back again to the country, with simpler needs and less "hustling" to satisfy them. However, such a condition is unattainable until Nature by its own methods rectifies the disturbed balance and produces the desired results. Meanwhile, we suppose all that can be done to stem the evil is to try to educate the people to the personal injury they are doing to themselves, and to preach contentment with simpler conditions of life.

ASPIDIUM SPINULOSUM IN TAPEWORM.

LAUREN (*Therapeutisch. Monatsch. Bz.*, April) has studied the effects of another relative of *Filaria*, the *Aspidium spinulosum*, in tapeworms. He extracted eight hundred and thirty-seven colored powder of the fern, obtaining a very fine granules of seed of a brown color. Of the same color the granules, so being as he was from the worm, and the color of the worm later took a dose of the powder. A very large *Brachycephalus litis*, about twenty centimeters long, came away with its head. Other specimens of the worm with it are referred to, and it was found that it was not a new record, but that it was a very common phenomenon. There was a record of a similar case in *Filaria*.

UNLICENSED PRACTICE IN A PARIS HOSPITAL.

THE Paris newspapers have recently discovered that an individual engaged in the oil trade has been practising medicine as a specialist in eye and ear diseases and as an accoucheur, and that he has been able to benefit himself substantially by referring to his connection with the Lariboisière, at which hospital he was for a long time one of the most assiduous attendants at the clinics, posing as a retired naval surgeon. After a time he was allowed to assist in dressing wounds, and finally in operations. It was at last discovered that he had no medical qualifications, and that he had already been fined for illegal practice, and then he got his *congé*. Several of our Paris contemporaries, including the *Progrès médical* and the *Gazette médicale de Paris* for May 13th, comment on this remarkable occurrence, and with perfect justice, it seems to us, complain of the laxity of administration which admits persons without any sort of credentials to the hospital clinics. It is undoubtedly an abuse to be guarded against most sedulously.

SCABIES OF THE CORNEA.

SUCH an affection as this is undoubtedly among the greatest of rarities. In a case reported by Sämisch (*Klinische Monatsblätter für Augenheilkunde*, 1898; *Presse médicale*, May 6, 1899) the lesion simulated a streak of keratitis and was treated accordingly, but without benefit. Then citrine ointment was employed. This aggravated the pain, but it seems to have loosened the acarus, a female with eight eggs, which was removed. The patient, a farm laborer nineteen years old, had no cutaneous manifestation of scabies, and none of his associates had any.

THE PRESERVATION OF SCIENTIFIC DOCUMENTS.

DR. MARCEL BAUDOUIN, in the *Gazette médicale de Paris* for May 20th, refers to a fire which recently occurred in the library of the French Chamber of Commerce which, while inconsiderable in itself, nevertheless resulted in the destruction of many important documents by fire and water. Dr. Baudouin pleads for incombustible libraries, and concludes with the remark: "If we were in New York, such a building would have been constructed long ago."

GENERAL MUSCULAR PARESIS DUE TO INFLUENZA.

TRULY, influenza is a protean disease as regards its manifestation and sequelæ. M. Boutry (*Bulletin de la Société médicale des praticiens*, January; *Nord médical*, May 1st) reports a case in which it gave rise to a generalized semi-paralysis that became serious by reason of its involving the respiratory muscles. It was five months before the patient could be considered as cured.

BUTTER AS A VEHICLE OF THE TUBERCLE BACILLUS.

It seems that absolute reliance can not be placed on past refutations of Obermüller's allegation that the butter found in the markets contains tubercle bacilli as a rule. Dr. L. Rabinowitch (*Deutsche medizinische Wochenschrift*, 1899, No. 1; *Centralblatt für in-*

nere Medizin, May 20th) reports the general freedom of Berlin butter from the bacillus, but says also that all the varieties of butter obtained from a certain large establishment contained the bacilli, together with unusually large numbers of other bacteria. We may infer, therefore, that it is not always the dairyman that is responsible for the contamination.

FLOWERS AND DISEASE GERMS.

At a recent meeting of the French Academy of Sciences (*Presse médicale*, May 10th) M. Domingos Freire stated that flowers harbored numerous saprophytic and pathogenic germs. In a rose he had found the *Streptococcus pyogenes*, and in another flower the *Bacillus pyocyaneus*. He suggested that there might be some subtle pigmentary relations between microbes and the flowers they infested, and declared that several sorts of microbes gave out the odors of such flowers. We hope that M. Freire's observations will not injure the florists' trade.

HYSTERICAL EXOPHTHALMIC GOÏTRE.

It is doubtless well to look upon exophthalmic goitre not as a distinct entity, but as the expression now of one morbid state and again of another. This was insisted upon by M. Debove at a recent meeting of the Hospital Medical Society of Paris (*Progrès médical*, May 6th). He related a case in which the affection seemed to have been of hysterical origin. It yielded readily to iodine injections.

THE TUNING FORK AS A TEST OF AUDITORY POWER.

It is somewhat unsatisfactory to be told that a patient could hear the ticking of a watch at a certain number of inches from the ear. At the recent meeting of the French Society of Otology, Laryngology, and Rhinology (*Indépendance médicale*, May 10th) M. Bonnier proposed the use of a tuning fork of a hundred double vibrations to the second. The proposal seems to us well worthy of acceptance.

MYELOSIRINGOSIS AND RECURRENT LUXATION OF THE SHOULDER.

It is well to bear in mind that in myelosyringosis, commonly called syringomyelia, habitual luxation of the shoulder is so common as to be of distinct diagnostic value. Dr. H. Schrader (*Beiträge zur klinische Chirurgie*, xxiii, 1; *Centralblatt für Chirurgie*, May 27th) reports two cases of his own, in only one of which was the initial dislocation of traumatic origin. On examination with the Röntgen rays, both the head of the humerus and the cotyloid cavity were found flattened. The author refers to thirteen other cases on record, six of which were first occasioned by injury, and five of which were known not to have been.

ITEMS.

The Richmond Academy of Medicine and Surgery.—

At the last regular meeting, on Tuesday evening, the 13th inst., a Report of a Case of Meningitis with presentation of patient was made by Dr. J. E. Warren.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending June 10, 1899:

DISEASES.	Week ending June 3.		Week ending June 10.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	13	5	12	3
Scarlet fever.....	214	11	188	19
Cerebro-spinal meningitis.....	0	13	0	12
Measles.....	420	19	422	30
Diphtheria.....	219	46	227	37
Croup.....	7	10	10	7

Change of Address.—Dr. Charles E. Nammack, from June 1st to October 1st, to Edgemere Crest, Far Rockaway, Long Island, N. Y.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending June 9, 1899:*

CRAWFORD, C. A., Assistant Surgeon. Detached from the *Peoria*, when put out of commission, and ordered to the *Wabash*.

FITTS, H. B., Surgeon. Detached from the naval hospital, Portsmouth, N. H., and ordered to the marine barracks, Sitka, Alaska.

DE VALIN, C. M., Passed Assistant Surgeon. Ordered to the naval hospital, Portsmouth, N. H.

DECKER, C. J., Surgeon. Promoted to surgeon from December 12, 1898.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Twenty-one Days ending June 8, 1899:*

BAILLIACHE, PRESTON H., Surgeon. Detailed to represent the service at the meeting of the American Medical Association, Columbus, Ohio, June 6 to 9, 1899.

BANKS, C. E., Surgeon. To proceed to New York for special temporary duty.

WEITENBRACK, C. P., Passed Assistant Surgeon. To proceed to Savannah, Georgia, for special temporary duty.

TABB, S. R., Assistant Surgeon. To proceed to Wilmington, North Carolina, for special temporary duty.

ANDERSON, J. F., Assistant Surgeon. Department letter of April 29, 1899, granting Assistant Surgeon Anderson thirty days' extension of sick leave from May 1st amended, so that said extension shall be for fourteen days from May 1 to May 22, 1899.

CORRIE, G. M., Assistant Surgeon. To report at Washington, D. C., for special temporary duty.

GAUS, HERBY, Hospital Steward and Chemist. To proceed to New York for special temporary duty.

SCOTT, E. B., Hospital Steward. To proceed to Wilmington, North Carolina, for special temporary duty.

MURRAY, R. D., Surgeon. Leave of absence granted by Bureau letter of May 11, 1899, temporarily suspended, and directed to proceed to New Orleans, Louisiana, for special temporary duty.

- CARTER, H. R., Surgeon. To rejoin station at New Orleans, Louisiana.
- CUMMING, H. S., Assistant Surgeon. Leave of absence for twenty-seven days granted by bureau letter of May 18, 1899, revoked from June 1, 1899.
- VON EZDORF, R. H., Assistant Surgeon. To rejoin station at New Orleans, Louisiana.
- FRICKS, L. D., Assistant Surgeon. Upon being relieved from temporary duty at Savannah, Georgia, to report to commanding officer, South Atlantic Quarantine Station, for duty and assignment to quarters.
- HUNTER, S. B., Acting Assistant Surgeon. Granted leave of absence for three days from June 7, 1899.
- WASDIN, EUGENE, Surgeon. To proceed to Washington, D. C., to render report as member of a commission detailed by the President for the scientific investigation of the cause of yellow fever.
- GEDDINGS, H. D., Passed Assistant Surgeon. To proceed to Washington, D. C., to render report as member of a commission detailed by the President for the scientific investigation of the cause of yellow fever.
- CORPUT, G. M., Assistant Surgeon. To proceed to Macon, Georgia, for special temporary duty.
- GAHN, HENRY, Hospital Steward and Chemist. To proceed to New York for special temporary duty.
- NEWBERN, WALTER, Hospital Steward. To proceed to the Tortugas Quarantine Station and report to medical officer in temporary charge, for duty and assignment to quarters.

Appointments.

- MOORE, DUNLOP, of Pennsylvania, and STANSFIELD, HALSTEAD A., of California, commissioned as assistant surgeons.
- BALLARD, JAMES C., of Mississippi, to be acting assistant surgeon, United States Marine-Hospital Service, for duty at Natchez, Mississippi.
- SLAUGHTER, A. W., of Wisconsin, to be Acting Assistant Surgeon, United States Marine-Hospital Service, for duty at Green Bay, Wisconsin.

Promotions.

- MCINTOSH, W. P., Passed Assistant Surgeon, commissioned as surgeon.
- THOMAS, R., Assistant Surgeon, commissioned as passed assistant surgeon.
- WICKES, H. W., Assistant Surgeon, commissioned as passed assistant surgeon.
- CUMMING, H. S., Assistant Surgeon, commissioned as passed assistant surgeon.

Obituaries.

LAWSON TAIT, F. R. C. S.

THE death is announced from England of Mr. Lawson Tait, F. R. C. S. Mr. Tait had a world-wide reputation as an abdominal surgeon of phenomenal capacity, and was, in fact, a most prominent pioneer of abdominal surgery. He was one of the earliest to discard all clamps and instrumental methods of dealing with the ovarian pedicle, and by adopting the method of ligating it and returning it to the abdominal cavity quickly reduced the average mortality of ovarian operations

below that attained by his colleagues in spite of his refusal to operate by Listerian methods. Mr. Tait may be said to have been really the pioneer of aseptic as distinguished from antiseptic surgery, his great motto being "Cleanliness, cleanliness, cleanliness."

Mr. Tait was born in Edinburgh in 1845, and was therefore in his fifty-fifth year. His early introduction to gynecological practice came through his association with Keith, of Edinburgh. He achieved a work which is not easily accomplished in England—namely, that of creating a world-wide reputation as a provincial surgeon, which attracted to the provincial city of Birmingham probably a larger *clientele* than was attracted by any metropolitan surgeon to London. He was a man of the most marked personality and strong individual characteristics, which caused him often to come to "loggerheads" with many of the chiefs of the profession, and created much animosity against him. But if his opponents were bitter, his friends were equally devotedly attached to him, and throughout the world at the present day are many brilliant leaders of abdominal surgery who are proud to call him master. He took a very active part in local politics in the city with which he was identified up to the time of his death. The list of Mr. Tait's professional honors is extensive. He qualified as a licentiate of the Royal College of Surgeons of Edinburgh in 1866, and became in turn M. R. C. S. Eng., F. R. C. S. Edin., F. R. C. S. Eng., M. D. (Hon.), New York, and M. D. (Hon.), Albany. He was a fellow of many English medical societies, a member of many American ones, and a foreign member of the Obstetrical Society of Berlin. For many years he was surgeon to the Birmingham and Midland Hospital for Women and professor of gynecology at Queen's College, Birmingham. His contributions to surgical literature were varied, extensive, and of great value. His loss will leave a wide gap in the surgical world, and he will be deeply mourned by his many personal friends, of whom the United States contains a large number.

Letters to the Editor.

GELSEMIUM IN THE TREATMENT OF INFLUENZA.

GRAND RAPIDS, MICH., May 30, 1899.

To the Editor of the *New York Medical Journal*:

SIR: Concerning the use of gelsemium in grippé, it may be of interest to add my testimony. During the recent epidemic I used it in nearly every case to which I was called early, and so uniformly favorable were my results that I was almost tempted to consider it a specific.

In no case in which its use was begun early did pneumonic symptoms develop. In several cases of sudden and severe onset, characterized by severe chill, suddenly high temperature, and the physical signs of the first stages of pneumonia, with the characteristic rusty sputum, all symptoms disappeared within thirty-six or forty-eight hours after treatment with gelsemium was instituted. I place great confidence in it.

My method is to give (to adults) one and a half or two drops of the fluid extract every half hour till the symptoms indicate that the full physiological effect is produced. It is not necessary to poison your patient.

EUGENE BOISE, M. D.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL.B.

XXIII.

RECOVERY OF COMPENSATION.

(Continued from page 828.)

Collections from Estates of Decedents.—There now remains to be considered before closing this chapter the manner of presenting and proving claims for physicians' fees against estates of deceased persons, together with a general survey of the law regulating the subject.

The administration of estates is governed in each State by statutes which are more or less peculiar to the particular jurisdiction. It will therefore be impossible in a limited space to give more than a very general view of the manner of administration, but the proving of claims, when contested, in which the doctor is most deeply interested, is governed by pretty much the same law in all jurisdictions, and will therefore be examined more particularly.

The first step in the administration of the estate of a deceased patient or debtor in which the doctor is interested is that at which the time arrives for presenting his claim for payment. Of the arrival of this time he is usually given notice, either actual or constructive. In the presenting of such claims the doctor should always be prompt, remembering that unless the claim is presented within the period fixed by the law of his State it is totally barred—at least, such is the law of many States—and that, should the law of his State, being more indulgent, allow him to present his claim after the first period fixed has expired, he will be entitled to his proportion of only those assets which remain after the payment of the claims filed and allowed at the proper time. The time fixed for the presentation of claims refers as well to those not due as to those which have already accrued. In some jurisdictions future debts of the estate are paid at their present value at the same time as the other debts; in others, arrangements are made for paying them at maturity.

Claim, by whom Presented.—The claim against a decedent's estate must be filed or presented by the person who owns it or has an interest in it, with the right of enforcing its collection,* or by his lawfully authorized agent.†

Claim, to whom Presented.—The presentation, to be beyond question, must be made to a legally qualified administrator or executor, although a presentation to an executor before his qualification has been held valid. A presentation to an administrator after his discharge is, however, of no effect.‡ When there are two or more executors or administrators of an estate, a presentation to one of them is sufficient. §

Presentation of Claim.—The sufficiency of the presentation of a particular claim is a question that can be

decided in the light of the statutes existing in that jurisdiction, and the preparation of a claim for presentation should never be undertaken without first consulting the statutes of the State in which it is to be filed. In some States the claim is not required to be presented in writing, although this is probably the exception. No harm can result from doing more than the law requires in matters of this kind, and the claim should therefore always be carefully prepared in writing, describing the general nature,* amount, and value of the services with as much particularity as possible. If a note or other instrument has been given, and the claim is filed upon such instrument, then a copy of it should be attached to the claim.

Claims for medical services should always be verified by affidavit of the claimant or doctor, sworn to before some officer having authority to administer oaths.

The affiant should in his affidavit of verification set up the facts that he is a physician and surgeon, and has been duly licensed or is duly qualified under the law of the particular State to practise medicine and surgery; that the annexed account against the estate of decedent, amounting to the sum of — dollars, is just, after allowing all just credits, deductions, and set-offs, and is now due and unpaid. An affidavit setting up these facts in proper form will comply with the law of nearly every State, but before making an affidavit the local statutes should be examined and their requirements carefully followed.

After a claim has been duly presented the executor or administrator will in most States examine the same, and, if he is satisfied that it is a just and proper claim against the estate, either in full or in part, he will allow the same, either at its face or *pro tanto*, accordingly as he is convinced of its merits.

Should the claim be rejected, either in full or in part, the claimant is required, within a short period of time, usually ranging from three months to one year, to bring an action against the executor or administrator to recover the claim or the part of the same which is disallowed; otherwise his rights in the premises will be barred.

Advisability of Prosecuting Claim.—At this point it becomes advisable to consider the condition of the decedent's estate and determine whether or not there are sufficient assets to pay the claim when proved, or whether the reward will be so small as not to justify the fight. Should the estate be solvent, it then is necessary to carefully scrutinize the claim and determine whether or not it is legally valid, and if valid, whether it can be proved.

Solvency of Estate.—In considering the solvency of the estate it is necessary to examine the order of the payment of debts, for the estate may be solvent as to a certain class of debts and pay them in full, while those of a subsequent class would be payable but a small percentage of their face value, or payers nothing at all. At common law the debts of a decedent were paid in the following order: 1. The necessary funeral expenses. 2. The necessary expenses of administration. 3. Debts of record due to the crown. 4. Debts of record due to the subjects, which included mortgages, decrees, statutes, and recognitions. 5. Debts of record not founded upon a valuable consideration. 6. Simple contract

§ Gibson vs. Mitchell, 16 Fla., 519.

‡ Dean vs. Duffield, 8 Tex., 235.

* The description of the nature of the service rendered should not be so specific, when filed in the State, holding professional communications privileged, as to violate the law.

† Debts by specialty are those arising out of a contract or other instrument under seal.

debts* based upon valuable consideration. 7. Voluntary bonds or covenants. 8. Other voluntary debts.

Under this scheme the physician's bill would rank in the sixth class, unless he had been so fortunate as to secure a bond in liquidation of it, when it would be advanced to the fifth class, or had reduced it to judgment during decedent's lifetime, in which case he would enjoy the advantage of belonging to the fourth class. In paying these debts, if the estate is solvent, all the creditors are paid in full; but if there is a deficiency in the estate, all the creditors of each class are paid in full in the order of their class until the estate is exhausted, those coming in the subsequent class or classes getting nothing, or perhaps only a *pro rata* share of their indebtedness. To illustrate, under the above scheme, an estate having only enough money to pay the first five classes of creditors would pay them in full. Should there, however, be a sum left after paying the first five classes, but not equal to the total sum of the debts owing under the sixth class, this amount would then be divided among the sixth class of creditors in proportion to the amount of their claims.

The common law order of creditors has been altered in every State, the preference of debts growing out of specialty contracts over those arising from simple contracts being nearly always withdrawn; in some States, however, judgments obtained in the lifetime of deceased are given the preference.

The most common order now existing in the United States is the following: 1. Funeral expenses. 2. Expenses of administration. 3. Expenses of last illness. 4. Judgments (abolished in a number of States). 5. Public debts. This order in many States ranks after the funeral expenses and expenses of administration. 6. Simple contract liabilities.

Probably the most striking change, as shown by comparison of the order existing at common law and the one above given, is the addition of the class "expenses of last illness." This class is quite generally recognized in the United States, but it is not universally accepted.

What is Included in Expenses of Last Illness.—Generally speaking, this includes the necessary medical attendance and nurse hire incurred during the last sickness. What the term "last illness" means is a question that is not entirely free from doubt. We have an early case from the supreme court of Louisiana in which, by reason of the peculiar statute defining the term "last sickness," a hardship is worked upon the physician. In that case the patient was afflicted with a fatal disease, of which the physician would have been unable to cure him, but the immediate cause of the patient's death was a pistol wound. The physician would have been entitled to a privileged claim for attending the patient during that which, in fact, was his last sickness; but the code specified that "the last sickness is considered to be that of which the debtor died,"† thus defeating the claimant's preference.

An early case comes to us from South Carolina in which a preference was asked for nursing during the decedent's "last sickness." The period of such services extended through the last year of the decedent's life, during which time he was lingering under the disease which finally terminated his existence. The refined and humane sentiment expressed by the court of appeals in giving their interpretation of this act demands a quotation

of the opinion: "The issue made up presented the question, and the jury have decided that the services were rendered during the last sickness.

"The court can lay down no rule or limitation for the duration of the last sickness of a man, nor for the degree of attention to be paid him. A wounded man may linger a long time in a helpless state, and chronic diseases and some cancers run through more time than a year. The act concurs with the principles of Christian civilization, and is remedial of a common want and necessity—attention and services during last sickness. We must therefore construe it liberally, and let it inure to its proper end, the full relief of the sick and the infirm. The court and the jury were the proper judges in the particular instance; and they appear to have assessed the amount of the plaintiff's account with justice and discretion."*

In the matter of Reese's estate the evidence showed that Mr. Reese received an injury from a fall; he was attended by the claimant for some time, and so far recovered as to be able to attend to his ordinary business, and the claimant's services were dispensed with. Afterward he had a relapse and called in another physician. Soon after that he died, probably from the effect of the fall, from which he never entirely recovered. The question arose whether claimant's bill was entitled to precedence as "medical attention giving during the last illness." The court thought that the clause refers to proximate and not remote causes of death, and that the attendance must be during the last sickness, but could not be rendered at intermittent periods.

In the case of Huse *vs.* Brown, *exr.*, the services were rendered by the claimant between January 19th and June 28th. The decedent was suffering from a cancer in his nose, from which he died in December following. The trial court instructed the jury that if they should decide the testator died of the cancer under which he was laboring when the plaintiff attended upon him, and that it was a continuing complaint or disorder until his death, they might consider it his last sickness. The supreme court, in referring to this instruction, said: "And why not, whether any such instruction had been given to them or not? It would seem to a plain understanding to be an indisputable fact that the sickness which is terminated by the death of a patient is his last sickness. . . . Sickness assumes so many forms, and death approaches in so many different ways, that we know not how to lay down any legal principle in such cases that can be applied by way of construction of the words 'last sickness.' What is to be considered a man's last sickness seems to be a question properly determinable by the jury upon the facts in each case, and which can seldom, if ever, be the same in two instances. There may probably be in a multitude of cases a strong resemblance. On a trial for homicide it is always a question for the jury whether the deceased died a natural death or in consequence of the act of the person accused. So it may be a question whether the sickness of which a person dies is the same under which he labored when confined and receiving medical aid one or two months before. In the case before us, the questions as to the cause of the testator's death and the continuance of his sickness have been settled by the jury whose business it was to settle it."†

In addition to the above opinion no comment is ne-

cessary. Should the estate be insolvent, and the services of such a character as to be urged as a preferred claim, or should the estate be solvent, then the next question to be considered is the validity of the rejected claim.

Validity of Claim against Estate.—Generally speaking, the same questions may arise to defeat the collection of a claim against the estate of a deceased person as those which are invoked by a living defendant for the same purpose, and which have been considered in the preceding chapters. For instance, it has been observed that the husband is liable for the medical treatment of his wife; for that reason a claim for services rendered to a deceased wife should be presented to the husband for payment, and not filed against her estate unless the husband has no property with which to pay the claim.*

There are, however, a few questions which, from the nature of the case, can only arise in the class of cases now under consideration.

Where services are rendered a decedent under the expectation and mutual understanding that compensation will be made for the same by way of legacy, or otherwise, but with no special agreement to that effect, the person rendering such services may, upon the failure of decedent to provide for such legacy, collect the reasonable value of his services from the estate.† But where the services are performed in the mere expectation or hope of a legacy, without the intention of making any charge therefor, no claim can be maintained against the estate, even though the claimant's hope of a legacy is not realized.‡

In case of claims of the sort rendered for members of the claimant's family there is a presumption that the services were intended to be gratuitous; this presumption, however, may be rebutted by proof of an express contract to pay therefor, or by evidence of facts or circumstances showing that when the services were rendered the parties contemplated a pecuniary compensation. The strength of this presumption is dependent upon the degree of relationship becoming weaker as the relationship is more distant.

Without dwelling further upon the character of the claim, which is regulated by the same law as that regulating claims between ordinary litigants, we will pass to the mode of proving these claims against estates of decedents, which presents new difficulties.

Proving Contested Claims against Estates of Decedents.—The manner of proving ordinary contested claims has been carefully examined in the last article, together with the amount and character of proof necessary to satisfactorily show the indebtedness. These same rules and precedents may all be considered as regulating the proof of a claim against the estate of a deceased debtor, with the single and important exception that in ordinary claims the physician himself is a competent witness to testify regarding the transactions out of which the indebtedness arose; while in a claim of this sort his lips are sealed and he can only prove his case by submitting his books of account and by producing such other competent witnesses as may have knowledge calculated to corroborate the account.

The reason for this condition is the following: At common law no interested party to a suit was a compe-

tent witness to testify in his own behalf. While the older law works laud the good sense and sound policy of this rule, it does not seem to have proved satisfactory in this country, for it has been abrogated by the legislature of every State, so as to permit the parties to a suit to freely tell all they know of the transactions or conditions out of which the litigation grows, the policy now being to consider the party's interest as affecting the credibility of his statements rather than disqualifying him from making such statements. It is obvious, however, that whenever a suit grows out of a transaction one of the parties to which is dead or insane, the grossest injustice might be done by permitting the other party to testify regarding the nature of such transaction, or to relate any conversation or communication which took place between them relative thereto. For this reason the modern lawmakers, in sweeping away the ancient rule disqualifying the parties as witnesses, have gone only so far as to permit them to testify where they are both living and mentally capable; but where the lips of one party are sealed by death or insanity they allow the law to stand as before, closing the mouth of the other.

This disability, together with the one imposed upon the physician by the law relating to privileged communications, is peculiarly serious to him. If the books of account disclose the nature of the patient's affliction or the character of the treatment prescribed, then they are objectionable in those States having statutes protecting privileged communications; if, on the other hand, the books contain no such information, or if such information is recorded in characters unintelligible to others than the physician, then they are subject to the criticism of being too indefinite to prove the account, and must be supported by strong corroborating evidence. Moreover, it is a matter of very grave doubt whether or not the physician may even prove his books of account and have them accepted in evidence in a suit against the estate of a deceased or insane person. In New York there are two distinct lines of conflicting decisions, one holding that the physician's books are admissible in evidence in a case of this sort,* and the other holding that the books can not be received in evidence.† There is probably no subject in the law upon which the decisions are more conflicting and the rights of the respective parties more uncertain and vague, nor in which the opportunities offer themselves for the lawyer to more fully exercise his knowledge, skill, and judgment in behalf of the interests of his client.

Is Physician's Wife Competent to Prove such Claims?—The person who is most commonly possessed of information necessary to corroborate such claims is the physician's wife, but whether or not she is a competent witness to prove the facts within her knowledge is a very nice question. At common law the wife could not testify for or against her husband in a suit to which he was a party. This rule has been altered in many States, but not in all. In those States in which the rule has not been altered the wife unquestionably has no right to testify. In those States in which the disability has been removed, and the wife permitted to testify with her husband, the question arises, in cases of this sort, whether her interest in her husband's suit

* *In re Wering's estate*, 100 Cal., 345, 31 Pac., 825.

against the estate of the decedent is such as to render her with her husband an interested party, and therefore an incompetent witness, or whether she shall be considered as having no interest, and accordingly permitted to testify.

The reasons given by the courts at common law for denying to the wife the privilege of testifying in a suit to which the husband was a party were, first, that it was against public policy, such an act being thought a menace to the harmony of the domestic circle and a violation of the confidence subsisting between husband and wife; second, because of the identity of their legal rights and interests. If this second reason is considered applicable to-day, there can be no alternative but to deny the wife the privilege of giving evidence in behalf of her husband's claim; but as the marked tendency of legislation during the past half century has been toward establishing a severalty of legal rights and interest, it is not surprising that some of our courts should consider the second reason so greatly weakened as to regard the wife no party to such a suit, and not legally interested in the result, and therefore accept her evidence in support of the claim. This is a question, however, upon which the courts are unfortunately divided, and in those States where a decision has not been rendered by the court of last resort the question must be considered as still open.

In cases of this sort the testimony of the wife has been held competent in the following States: Maryland,* Mississippi,† New Hampshire,‡ and New York.* It is probable that the rule would be held the same in Nebraska.¶

On the other hand, such testimony has been held incompetent, and rejected by the courts of last resort in the following States: Illinois,‡ Indiana,§ Iowa,¶ Maine,§ Pennsylvania,‡ and West Virginia.**

The claimant, upon producing satisfactory proof of the legality and justness of his claim, is entitled to a judgment for the amount he has shown to be due to him, which judgment the executor or administrator must pay in due time, either in full or in part, as the assets of the estate may justify.

Pith of Current Literature.

Cerebro-spinal Meningitis confounded with Eclampsia.—E. Müller (*Hospitalsblende*, March 22, 1899, p. 295; *Scottish Medical and Surgical Journal*, June) records the case of a thirty-four-year-old woman in a

state of profound coma, who was admitted to Professor Horwitz's clinic in the eighth month of her second pregnancy. Two days previously she had felt out of sorts and next day had a few shiverings. On the morning of admission she was found unconscious on the floor and had several convulsions. On admission she was not in labor; there was no edema; lungs and heart were normal; the pulse was 100, tense and forcible, and the temperature 99.3° F. She got morphine for restlessness, and slept quietly. In the morning she had a typical convulsion. Catheterization gave eight hundred grammes of urine showing the albumin reaction moderately and containing a few granular casts. Temperature in morning 101° F., rose suddenly to 104° F., with the pulse quick and tense; five hundred grammes of blood were drawn, but, as the condition was unsatisfactory, she was delivered by Cæsarean section (fundal incision) and afterward received an injection of five hundred grammes of saline solution. The pulse, however, grew weaker and she died. On autopsy the heart was found to be natural, the lungs congested and cedematous. The kidneys showed parenchymatous and fatty degeneration; the spleen was not large. The brain had gelatinous yellow pus along the vessels in the sulci, and the vessels were congested. There was no fluid in the ventricles. A bean-shaped diplococcus was found and cultivated from the pus. A possibility of meningitis had been glanced at, owing to the existence of an epidemic at the time.

The Significance of Oxaluria.—Dr. Robert F. Williams (*Maryland Medical Journal*, May 20th), from a lengthy consideration of the subject, draws the following conclusions:

1. Whereas the appearance of oxalates in the urine—excluding their ingestion in foods—is due to a derangement of digestion or metabolism, this derangement probably has its cause in many cases in functional nervous irregularity, which may or may not be so great as to produce general nervous symptoms, and if these are present they are not necessarily caused by the oxalates.

2. The condition causing the appearance of oxalates in the urine may produce symptoms closely simulating the constitutional symptoms of Bright's disease.

3. The excretion of oxalates by the kidney for a short while may occasion no local disturbance of that organ, but if continued may, by irritation, cause the appearance of albumin and casts with lessened urine, corresponding to the urinary symptoms of Bright's disease, and if unchecked may lead to permanent destruction of kidney tissue and true Bright's disease.

4. In all suspicious cases, in which the nephritic symptoms are accompanied by the appearance of oxalates in quantity, diagnosis should be held in abeyance and the oxaluria overcome by appropriate remedies to exclude this as a possible cause of the symptoms before making a positive diagnosis and pronouncing a necessarily hope-dispelling prognosis.

Poisonous Properties of Orthoform.—The *Indian Medical Record* for May 3d says that it published in its issue for April 12th an article by Dr. W. Asam showing that orthoform was capable under certain circumstances of giving rise to symptoms of general poisoning.

Similar effects have been observed in the clinics of Albertin, Pollosson, and Rollet, of the Lyons Hospital.

In the case of a woman under the care of M. Al-

bertin, where an external wound existed after abdominal hysterectomy, orthoform was by a mistake used instead of xeroform. The patient was soon afterward attacked with headache, fever, nausea, and vomiting, while on the face and other parts of the body patches of erythema of a dusky red color appeared. The wound was carefully washed, and all the bad symptoms disappeared in three days. Similar symptoms were noticed in a patient operated on by M. Pollosson for a canceroid of the nose, and in two cases of burns dressed with orthoform (Rollet).

From this, the *Record* says, it appears that, when applied to extensive surfaces, orthoform becomes dissolved in the alkaline products of secretion, and may produce poisonous effects which, though not dangerous, are unpleasant. Consequently orthoform should be employed in small quantities only, and with caution.

New Operation for Inversion of the Uterus.—Westermarck (*Centralblatt für Gynäkologie*, 1899, No. 1; *American Journal of the Medical Sciences*, June) opened the posterior fornix, inserted one finger into the ring from above, and, while steadying the uterus in this way, incised the posterior wall. By compressing the anterior wall with the thumb while the edges of the wound were pressed forward, the inversion was easily reduced. The uterus was then brought through the vaginal opening, and the wound sutured with catgut, after which the organ was replaced within the peritoneal cavity and the wound in the posterior cavity and the posterior fornix sutured. The patient made a good recovery.

A Cause of Crying in the Newly Born.—Dr. Thomas S. Southworth (*Archives of Pediatrics*, March) records the case of a newly born child in which incessant crying was found to be associated with priapism. The placing of a cool hand over the bladder was found to be associated with discharge of turbid brown urine. The child was ordered boiled water sweetened with cane sugar every two hours. The author says: It is extremely probable that much of the supposed pain of colic in the newborn for which they have, from time immemorial, been dosed with fennel and other aromatic teas, is due to these sources of irritation in the kidney, ureters, bladder, or urethra. Boiled water, which should be given to every infant at regular intervals, for more reasons than one, pending the establishment of lactation, will dilute the urine and prevent or alleviate the discomfort. The rather unusual opportunity afforded the writer of observing matters in this case, together with the subsequent course of events, point clearly to the urine as the cause of the crying, whereas, had no such observation been made, hunger and miction might readily have been considered a sufficient explanation of the symptoms.

The Treatment of Pulmonary Tuberculosis by Subcutaneous Injections of Camphorated Oil.—Dr. Bruno Alexander (*Gazette hebdomadaire de médecine et de chirurgie, Revue médicale*, May 24th) says that camphor influences all the symptoms of pulmonary tuberculosis and is thus one of the best agents in its hygienic treatment, inducing in about eight days the quieting of nervous troubles, headache, and insomnia. It continued longer, the congestive symptoms of the lungs disappear. In patients with fever Dr. Alexander injects daily *sub cut* from fifteen to thirty one hundredths of a grain of camphor, or one or two Pravaz syringeful of cam-

phorated oil, continuing the treatment for from four to six weeks without interruption, at the end of which time he ceases for from one to four weeks, resuming treatment later. When the fever has disappeared he raises the dose to from forty-five to seventy-five hundredths of a grain during one or two weeks without interruption. This treatment is said to be always well supported, and even hæmoptysis is not a contraindication. The author compares the value of camphor in lung diseases to that of digitalis in heart affections.

Central Pneumonia discovered by the Radioscope.—

G. Variot and G. Chicotot (*Journal de clinique et de thérapeutique infantile*, vol. vii, p. 151, March 9th; *British Medical Journal*, May 13th) describe the case of a girl, aged nine years and six months, who had been ill for five days, who had slight pain at the base of the thorax, loss of appetite, cough, furred tongue, and some diarrhoea. There was an evening temperature of 103.2° F. Percussion and auscultation practised with great care gave negative results on both sides of the chest. The presence of labial herpes, however, and the temperature, suggested central pneumonia, especially as the respiration was not specially quickened. The next day the temperature fell to 100.4° F., and the next day to 98.6° F. Then the use of the Chabot-Villar tube was called in to aid the diagnosis by radioscope. It was seen quite clearly that in the middle of the right lung was a zone of opacity about the size of a five-franc piece. This was doubtless a pneumonic patch in process of regression.

Treatment of Keloid by Injections of Creosote in

Oil.—Balzer and Mousseaux (*Annales de dermatologie et de syphiligraphie*, 1898, No. 12; *American Journal of the Medical Sciences*, June) report a case of keloid of the lobule of the ear, following the removal of a small tumor, successfully treated by injections of a twenty-per-cent. solution of creosote in olive oil. At each *séance* about one cubic centimetre was injected into different parts of the keloidal tumors, of which there were two. These injections were followed by very little pain, but a few days after the first one a portion of the keloidal tissue sloughed out, leaving a deep ulcer, which soon cicatrized. At the time of making the report the smaller of the two tumors had entirely disappeared and the larger was considerably reduced in size.

Book Notices.

Gout: Its Pathology and Treatment.—Founded on the Goulstonian Lectures on The Chemistry and Pathology of Gout, delivered by the Author before the Royal College of Physicians of London in 1897; with the Addition of Some Recent Investigations concerning the Treatment of Gout, and a Detailed Account of the Treatment of the Various Forms of Gout. By ARTHUR P. FULTON, M.D. (Lond.), B.Sc., F.R.C.P., Physician in Charge of Out-patients and Lecturer on Forensic Medicine at St. Mary's Hospital, New York. W. B. Saunders & Co., 1899. Pp. viii + 248.

With the introduction of this work it is probable that many of our colleagues are familiar, for it is practically a reproduction of the Goulstonian Lec-

tures for 1897 on The Chemistry and Pathology of Gout. The opinion they have formed of them must necessarily have been favorable, we think, and the pages that have been added to make the work complete and as it now appears in book form are not likely to cause them disappointment.

In the second part of the book we are given an excellent presentation of the causation, the forms, the diagnosis, and the prognosis of gouty disorders. It is not unconventional. Part III, however, is unusual, and, since it represents the result of investigations conducted by a competent observer, it is valuable in no ordinary degree, however surprising it may be in many respects. The pages describe "a series of investigations undertaken with the objects of ascertaining the various conditions affecting the formation and removal of gouty deposits, the influence of alcoholic drinks on the gouty process, the solvent effect of the mineral constituents of various vegetables on gouty deposits, and the value of certain drugs in effecting the removal of such deposits." The author's conclusions in connection with these matters are of sufficient importance to be quoted at length.

"1. The alkalinity of the blood is apparently not appreciably diminished during a gouty attack.

"2. The solubility of uric acid in the blood is not affected by a diminished alkalinity of the blood produced by the addition of organic acids.

"3. The deposition of sodium biurate is not accelerated by a diminution of the alkalinity of the blood.

"4. An increased alkalinity of the blood does not increase the solubility of deposits of sodium biurate.

"5. The gout-inducing properties of certain wines are not due to their acidity. Probably they owe their gout-inducing action to the effect they exercise on the metabolism of the liver.

"6. The solubility of sodium biurate is markedly increased by the presence of the mineral constituents of most vegetables.

"7. The solubility of sodium biurate is diminished by the presence of the mineral constituents of meat.

"8. The mineral constituents of certain vegetables delay the conversion of sodium quadriurate into the biurate.

"9. The vegetables most useful to gouty subjects are spinach, Brussels sprouts, French beans, winter cabbage, Savoy cabbage, turnip tops, turnips, and celery.

"10. The administration of the ordinary alkalies, of lithium salts, of piperazine, and of lysidine, with the object of removing gouty deposits, appears to be useless.

"11. No general acidity of the system is associated with gout.

"12. No relationship exists between the acidity of the urine and the alkalinity of the blood.

"13. The administration of salicylates with the object of removing gouty deposits appears to be useless, and their employment in the treatment of gout is contraindicated.

Part IV, which describes the treatment of gouty disturbances, is delightful because of its common sense and its simplicity. After what has preceded, it is not to be expected that the author should place great dependence upon treatment by drugs, though colchicum is naturally an exception, particularly in the acute form of the disease. One statement, we believe, will seem to one surprise, and that is that "a patient suffering from gout should avoid, as far as possible, the use of common salt at table, owing to the power it pos-

sesses of diminishing the solubility of sodium biurate, and thereby hastening the precipitation of that body."

The volume is most scholarly throughout.

The Anatomy of the Central Nervous System of Man and of Vertebrates in General. By Professor LUDWIG EDINGER, M.D., Frankfurt-on-the-Main. Translated from the Fifth German Edition by WINFIELD S. HALL, Ph.D., M.D., Professor of Physiology in the Northwestern University Medical School, Chicago. Assisted by PHILLO LEON HOLLAND, M.D., Instructor in Clinical Neurology in the Northwestern University Medical School, Chicago, and EDWARD P. CARLTON, B.S., Demonstrator of Histological Neurology in the Northwestern University Medical School, Chicago. Illustrated with Two Hundred and Fifty-eight Engravings. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1899. Pp. xi-446.

It is now fourteen years since the first appearance of Edinger's *Lectures on the Structure of the Central Nervous Organs*. This period has been one of active progress in our knowledge of the architecture of the central nervous system. New techniques in the hands of such men as Ramon y Cajal, Golgi, and Nissl; researches in embryology and comparative anatomy by Retzius, His, Flechsig, and many others, to say nothing of our increased familiarity with form relations obtained through older methods, have, by adding new facts to neurological science, greatly widened the horizon of its philosophy.

Over three hundred years ago Descartes, the father of modern neurology, the man who did not "mirror the actuality of his own age, but who embodied its potentiality and magically reflected the future," foresaw that many of the dark corners of metaphysics were to be redeemed by the searching lights of the natural sciences, and foresaw that of these lights the most penetrating, the most illuminating, was the one which was lit by the study of the nervous system. The credit which must ever belong to the great Frenchman is only enhanced by the length of time elapsing before the fulfillment of his prophecy. The present century was well on its way before the finer structure of the nervous system began to be revealed, and still further advanced before it was possible to harmonize the make-up of the machine with its workings. Now, if one looks only backward, much has been accomplished. The associated results of the labors of anatomists, physiologists, and pathologists, of psychologists and clinicians, together with the facts gleaned from embryology, from biology, and indeed from all the sciences which deal with life, have narrowed the domain of metaphysics and have shown that, as the nervous system is the last link in the material chain, so through a knowledge of it we are to approach most closely to the unknowable.

The history of the book now before us reflects the fruitful activity of its lifetime. Begun as a series of lectures by a practising physician in Frankfurt, it has come through five successive editions until to-day, in enlarged form and with widened scope, it stands as one of the best known of purely scientific medical books. Originally a description of the central nervous system of man intended especially for physicians, it now contains information indispensable to all who occupy themselves with the problems connected with the manipulations of nervous energy. In addition to being a masterly

description of the comparative anatomy and embryology of the nervous system, it is marked throughout by philosophical suggestions and deductions which will be appreciated by all inquirers.

The translators have done their work well. The text reads easily, with remarkably few places where the meaning is not instantly plain.

Essays for Students. By STEPHEN PAGET, F. R. C. S., Surgeon to the West London Hospital, etc. New York: William Wood & Co., 1899. Pp. 7 to 177.

"THESE essays were written for students," says the preface, and indeed they are excellent, lacking as they do that air of finished perfection and the odor of the lamp which hangs about so many so-called clinical lectures; lectures many of which have probably never been delivered. They include four different groups of diseases—namely, strangulated hernia, cancer of the breast, one entitled "Some Run-over Cases," and, lastly, a set of lectures on the practical elements of aural surgery. Specially interesting is the study of the "run-over cases," many of which developed for some unknown reason an excessive and voracious appetite or thirst not in any way dependent on post-traumatic diabetes, but apparently connected in some manner with the injury to the brain which these patients received. The same condition is sometimes seen in cases with brain tumors.

Les Glycosuries non diabétiques. Par GERMAIN ROQUE, Professeur agrégé à la Faculté de médecine, etc. Paris: J.-B. Baillière et fils, 1899. Pp. 5 to 92.

UNDER the leadership of the famous Claude Bernard, the French school of medicine has always occupied a leading place among the investigators of the causes and results of the presence of sugar in the urine. Especially has this been true of recent years and on the limited subject of non-diabetic glycosuria. Among those who have devoted their energies to the solution of this problem the author of this small volume is not the least, and he has here given a most excellent and critical review of the whole matter, to which have been added the special points observed by himself. The divisions of the subject are four: Gouty, digestive, nervous, and puerperal glycosuria, with a chapter on treatment. Under the division of digestive or alimentary glycosuria, the habit which some authors have adopted of regarding the easy production of this form of glycosuria as an accurate index of the glycolytic function of the liver is sharply and justly criticised, and the results are shown to be dependent far more on the glycolytic powers of the general body tissues than on any special organ, such as the liver. The treatment of the various forms is well presented and the volume should prove a useful one.

Die neuere Geschichte der Medicin. Kurz dargestellt von O. v. BOLTENSTEIN, in Bremen. Leipzig: C. G. Naumann, 1899. Pp. vii, 398. [*Medizinisch-Bibliothek für praktische Ärzte*, Nr. 112, 113.]

THIS book is a most excellent exposition of one graphical fact, salient in the history of medicine, but, at the same time, it is more than a mere collection of the lives of men whose names have become a tradition. It records what these men did and what they thought, but it also considers the slow acting causes which made the efficiency of their labors possible. It is philosophi-

cal. The accomplishment of this difficult task in so small a volume is no little achievement, and the book bears throughout the marks of extreme research. It can be warmly recommended as a satisfactory, trustworthy, and yet brief treatise upon a subject with which we should do well to make ourselves more familiar.

Veröffentlichungen aus dem Gebiete des Militär-Sanitätswesens. Herausgegeben von der Medizinal-Abtheilung des königlich preussischen Kriegsministeriums. Heft 13. Kriegschirurgen und Feldärzte des 17. und 18. Jahrhunderts. Von Professor Dr. ALBERT KOEHLER, Oberstabsarzt I. Cl. Mit 13 Portraits, 5 Abbildungen, und 2 Plänen. Berlin: August Hirschwald, 1899. Pp. x+269.

THIS volume of the publications of the medical division of the Prussian war department is a portion of a series devoted to the history of military surgery and the military surgeons of Prussia and the other German states, and the present volume contains the lives of the military surgeons of the seventeenth and eighteenth centuries. It was a time of great military activity, as it includes the Seven and the Thirty Years' wars, and the crude military surgery of that time made considerable strides, though the means employed in the treatment of wounds seem curious enough now. The work is embellished with a number of portraits and pictures from old books of the time.

Annuaire des eaux minérales, stations climatiques et sanatoria de la France et de l'étranger. Suivi d'une nomenclature des établissements hydrothérapiques. Par le Docteur G. MONTEY, vice-président de la Société d'hydrologie médicale de Paris, etc. Quarante et unième année, 1899. Paris: Librairie Maloine Pp. 5 to 287.

THE appearance of the forty-first edition of this guide is a sufficient evidence of its popularity and usefulness.

Die multiple Fettgewebsnekrose. Klinische und experimentelle Studien. Von Dr. ARTHUR KATZ und Dr. FERDINAND WINKLER, Assistenten an der allgemeinen Poliklinik in Wien. Mit 15 Abbildungen. Mit einem Vorwort von Dr. LEOPOLD OSER. Berlin: S. Karger, 1899. Pp. 139.

THE authors have reviewed the literature and the cases so far published of multiple fat necrosis, and have also carried out a number of experiments on dogs in which injury was done to the pancreas, and fat necrosis thus produced. Their results do not entirely settle this difficult and little-understood branch of pathological anatomy. They are as follows:

Multiple fat necroses occur more often in men than women, and in stout and athletic men especially. They are caused by the action of a sharp instrument which is set free when the pancreas is injured, or a foreign body takes place in its position. In both cases there is a sharp laceration, the blood vessels are torn, circulatory, and there is a freedom of contact with peritoneal fluid. The necrosis of the fat is generally only a moderate reaction to the injury. There is no evidence of a reaction on the part of the pancreas. The diagnosis is established by the following: (1) the symptoms pointing directly to the pancreas, (2) the site of the lesion, the position of the pancreas, (3) the effect of the

obstruction. The only treatment which has been followed by any results is exploratory laparotomy. Its method of action is, however, unknown.

Footnotes to Evolution. A Series of Popular Addresses on the Evolution of Life. By DAVID STARR JORDAN, Ph. D., President of Leland Stanford Junior University. With Supplementary Essays by EDWIN GRANT CONKLIN, Ph. D., Professor of Comparative Embryology in the University of Pennsylvania; FRANK MACE MCFARLAND, Ph. D., Associate Professor of Histology in Leland Stanford Junior University; and JAMES PERRIN SMITH, Ph. D., Professor of Paleontology in Leland Stanford Junior University. New York: D. Appleton and Company, 1898. 1p. xviii-392. [Price, \$1.50.]

THERE have been two voyages in the history of science which are especially memorable: the one by Columbus which practically demonstrated the earth's shape; the other, a far less well known voyage, but one perhaps more far-reaching in its results and of more remarkable value to science, the voyage of the *Beagle*. The voyage of Columbus opened to the Old World new fields for exploration and for material development and the results to pure science have been very great; but the voyage of the little ship *Beagle* was the means of opening a way by which the methods of Nature could be made clear and their laws reduced to a form with simple terms. The man who first did this was Charles Darwin, and his inspiration was received during the voyage of the *Beagle* by observing the strange fact that the land birds of the Galapagos Islands off the coast of South America resemble exactly no other known species, though they mimic very closely in characteristics and habits the land birds of the continent some six hundred miles away. Evidently they have been carried out to these islands on drift timber or blown out by some storm. Why, then, are they different from their ancestors? The answer to this question took Darwin many years of patient observation and quiet thought, but the result was commensurable to the effort, for practically no fact which he recorded and used has been controverted. The answer was Evolution, an idea as old as the Greeks, whose sterile philosophy stopped with the mere dream of the possibility, and it was left to Darwin to wrest from Nature a few slight hints only of the secret of her laws. About this much-misused word has centred a war, chiefly of words. The scientific man is too busy verifying its application to natural life and endeavoring to obtain more accurate glimpses of the meaning of this process to spend much time in debate, but to the lay mind it has been a source of great joy. This type produces marvelous Darwinian religions destined to supplant all others, social evolutions which contain no evolution, so that the name has lost its original significance and is commonly supposed to be a force which carries us somehow upward away from our monkey ancestors. In contrast to this sort of thing a few minds have endeavored to stem the current and to popularize the truth. Among these may be mentioned more especially Huxley, Tyndall, and Spencer in England, and many others in our own country. Foremost among the latter must be placed these essays of Jordan's, which in clearness of form and reasoning leave little to be desired. All but three of the papers in the volume have been written by him as condensations from a series of University Extension lectures. They are social in

their trend, showing the general applications of the principles of evolution to our modern life, as a few of the titles will show—The Evolution of the Mind; Hereditary Inefficiency; The Woman of Evolution and the Woman of Pessimism. Our author touches all these varied subjects with a light hand; they are clear and simple in their presentation, yet scientifically true—a rare combination. Yet they are not mere literature, on the other hand, but sound discussions of scientific problems. The essays contributed by the collaborators are less successful only because their subjects are more purely technical.

Les Régénérations d'organes. Par le Dr. PAUL CARNOT, Docteur ès sciences, etc. Avec 16 figures dans le texte. Paris: J.-B. Baillière et fils, 1899. Pp. 5 to 96. [Price, 1 fr. 50.]

THIS is an excellent little reference monograph on the little-known but important subject of the regeneration of the tissues after injury or disease. The literature of the subject is given in a very complete way.

Diseases of the Ear, Nose, and Throat, and their Accessory Cavities. By SETH SCOTT BISHOP, M. D., D. C. L., LL. D., Professor of Diseases of the Nose, Throat, and Ear in the Illinois Medical College, etc. Second Edition, thoroughly revised and enlarged. Illustrated with Ninety-four Colored Lithographs and Two Hundred and Sixteen Additional Illustrations. Philadelphia, New York, and Chicago: The F. A. Davis Company, 1898. Pp. xix-3 to 554. [Price, \$1.]

THE fact that the author has been called upon to prepare a second edition within less than two years after the issue of the first shows that his book has filled a want among at least a portion of the readers of this special field of medical literature. Dr. Bishop stated in his first edition that his work was designed not primarily for specialists, but for students, for general practitioners who wished to acquire the proficiency necessary to properly treat those patients who were unable to visit specialists, and for those who were gradually exchanging their general work for special.

This statement designates the point of view from which the book should be judged. Necessarily it can not be compared with more elaborate treatises, for it is not designed to cover the same ground. But for a working volume for frequent consultation, by the special classes for whom it is designed, it is thoroughly up to date, and contains the experience of one who has done a vast amount of clinical work and has been able to deduce therefrom logical conclusions which he has stated in a clear and comprehensive form.

The second edition contains fully twenty-five per cent. more matter than the first. Entirely new chapters have been prepared on two important topics—viz., Related Diseases of the Eye and Nose, and Life Insurance affected by Diseases of the Ear, Nose, and Throat. Moreover, there have been added illustrated articles on Direct Laryngoscopy or Autoscopy, and on Pachydermia Laryngis. Illustrations have been used with a lavish hand and the colored plates are of unusual merit.

We have reason to know that this work has met with a large sale among the physicians of the South and West. Other works similar in scope and written by Eastern men are perhaps better known and more widely read by the profession in the Eastern cities, but Dr.

Bishop has prepared a treatise which any worker in these special fields can read with profit. We are sure that he will do so with interest also.

Clinical Lectures delivered before the Students of the Imperial Moscow University. By G. A. ZACHARIN, M. D., Late Professor (Emeritus) of Clinical Medicine and Director of the Therapeutical Faculty Clinic of the Imperial Moscow University, etc. Translated from the Fifth Russian Edition by ALEXANDER ROVINSKY, M. D., Member of the Massachusetts Medical Society. Boston: Dampell & Upham, 1899. Pp. xvi-187.

THESE lectures, delivered to the students of the Moscow University, certainly afford an excellent example of what real clinical lectures should be. They not only present a case and bring out its salient points, but they go much further in giving to the student clear instruction in the methods of obtaining a complete clinical picture, the value of observing the small details of the surroundings and daily life of the patient, and the method of sifting the whole mass of evidence obtained. An example of the application of this process is seen in the first series of lectures, twelve in number. These are all devoted to the study of a single case, not a very interesting one at first glance, with chronic gastritis, anemia, and oxaluria, all of which can be more or less closely traced to the poor food, bad air, and hard work of the Russian peasant. Yet, while watching the gradual improvement of this one case for a period of three months, the author practically covers the whole subject of the care and hygiene of cases of chronic intestinal trouble, of massage, of drugs, of the modern methods of chemical analysis as applied to gastric conditions, and of the use and abuse of mineral waters. Such a method of instruction involves a great expenditure of time, yet it is certainly better than the present idea of showing five or six cases in an hour, with great effect theatrically, but with a result sadly muddling to the average student brain. We can confidently recommend these lectures to every clinical teacher as extremely suggestive, even though they are not altogether in accord with the current views of the profession.

The Diseases of the Nervous System. A Text-book for Physicians and Students. By Dr. LEONIE HERT, Professor at the University of Breslau. Translated, with permission of the Author, by AUGUST HOCH, M. D., formerly Assistant Physician to the Johns Hopkins Hospital, etc., assisted by FRANK R. SMITH, A. M. (Cambridge, M. D., Instructor in Medicine in the Johns Hopkins University. With an Introduction by WILLIAM OSTER, M. D., F. R. C. P., F. R. S., Professor of Medicine in the Johns Hopkins University, etc. With One Hundred and Eighty-one Illustrations. New York: D. Appleton and Company, 1899. Pp. xvi-715. [Price \$8.00.]

WITH the exception of several new cut and colored alterations in the arrangement and addition to the substance of the text, Dr. Hert's second edition is the same as the first. On its first appearance, in 1890, it at once took a high rank as a text-book of nervous diseases.

Its popularity at home, in England, France, and Italy, but especially in this country, rendered it a notable review in these columns unnecessary. It is now

so well known that the only introduction necessary is the announcement of this second edition.

Die Krankheiten der Mundhöhle, des Rachens und des Kehlkopfes. Mit Einschluss der Untersuchungs- und Behandlungsmethoden. Für praktische Ärzte und Studierende. Von Dr. ALBERT ROSENBERG, in Berlin. Zweite neu durchgesehene und erweiterte Auflage. Mit 180 Abbildungen im Text. Berlin: S. Karger, 1899. Pp. x-2 to 412.

THE second edition of this valuable text-book on the diseases of the mouth, throat, and larynx has been considerably increased in size by the addition of new illustrations and the results of the more recent studies on the subject. It still maintains its position as one of the best books of its sort, being clear, concise, and sound in its statements.

Miscellany.

The Rush Monument Project.—At the recent meeting of the American Medical Association the following communication was submitted:

Mr. President and Members of the American Medical Association: You may remember the enthusiasm which prevailed at the meeting of the association in Philadelphia when the sum of a hundred thousand dollars was fixed by common consent as the amount which should be contributed by the profession to erect a suitable memorial, not alone of the great medical patriot of the Revolution, but of the part which the profession of medicine, represented by him, had had in the foundation of this great republic, and as the expression of the patriotic sentiments and love of country of the medical men of the present day. You must also recollect how the delegates from State after State rose and pledged their several constituencies each for its quota for this commendable project. You may further remember how at the meeting in Denver two States, New York and Colorado, redeemed that pledge, and a third, Pennsylvania, conditionally, and how at my request the permanent secretary was directed to communicate with the officers of the State medical societies, urging them to appoint without delay representative members of the committee from their several States and Territories. I know that he promptly performed this duty. Sixty State medical societies have appointed such representatives. Three hundred and fifty-five dollars and fifty cents have been added to the movement fund, which now by increase of interest upon the money already accumulated amounts to about ten thousand dollars, actually in the treasury of the U. S. A. Washington dispatch reads: "For the monument to Lafayette, a sum of ten thousand and two hundred dollars was today pledged. It was received at the office of the Lafayette Monument Commission from the Ohio State Congress. The sum of \$10,000 contributed by the Ohio Legislature, \$2,000 for the monument to Lafayette, and \$8,000 for the city of Paris in the year 1900. When the figures sent direct from various schools, the total of the second dollars." "One half the fruit of the harvest is to be given a hundred thousand men, and the other half profession in the United States to be given to their own national capital to their government and profes-

sional *confrère*, whose services in the cause of national liberty were every whit as great.

Your business committee at Denver did not approve my request that the association should defray the expense of attendance at the meetings of at least one of the officers of the Rush Monument Committee. As these officers have continued over from year to year, it is evident that the action of the business committee virtually requires them to contribute annually from their private means from fifty to two hundred dollars, according to the distance traveled. In my own instance, by reason of my retirement from active duty in the navy by limitation of age, I am no longer eligible for official detail and should be subjected to an outlay on account of the monument which no other member of the association is asked to make.

Mr. President and Members of the Association—after fifteen years of persistent, earnest effort, the time has come when I must admit that I can do no more. I reminded you at Philadelphia that, of the eleven men originally interested in this project, all but two had died since its inception. In February of this year, the secretary of the committee, Dr. George H. Rohé, of Maryland, my friend of friends, my always enthusiastic colleague and active coadjutor, also died; so, lest death come unaware to me as it did to him, it is advisable that I transfer this duty to some younger and I hope more successful worker. It has been from the first a labor of love for me. From the beginning of my professional life, and this was almost half a century ago, the personality of Rush has been familiar to me through my preceptor, Dr. Rush Van Dyke, whose father, Dr. Frederick A. Van Dyke, a courtly, cultured gentleman of the highest type of the old-time physician, was himself a favored pupil of Benjamin Rush's, whose name he bestowed upon his son, for whom he selected the honorable career which his famous teacher and himself so worthily graced. I would that every physician of this day should appreciate his indebtedness to this great man, who, had he lived among us, would have been no less distinguished—this physician who, great when he lived, is still the greatest physician this country has ever produced—this typical, manly doctor, whose faults were those which belong to every man of his impetuous, earnest, far-seeing, and far-striving nature. To honor him with a monument is to honor our profession—and it must be a monument in keeping with the dignity of this greatest of human vocations—hence I felt you acted wisely at Philadelphia in determining a hundred thousand dollars as the proper sum to be devoted to its erection.

The secretary of the navy has assigned an unequalled site for the structure on the beautiful park fronting the United States Naval Museum of Hygiene, especially appropriate in that Rush was a pioneer in sanitary science, which men like the surgeon Gross and the physician Flint, as they laid down their lives, declared to be the highest aim and crowning glory of the science of medicine.

At the sluggish rate at which this fund has grown in my hands, it would be futile for me to see it reach the proportions I think, with you, it should attain, especially as I shall have left for an indefinite residence abroad when this report is presented. So, thanking you for your repeated expressions of approval of the little I have done and of the much I have sought to do, and cordially wishing success to my successor in office, I hereby resign the trust with which you first honored

me in 1884 and have repeatedly renewed the past fifteen years.

Respectfully submitted,

ALBERT L. GHION, M. D.,
Chairman, Rush Monument Committee.

A New Operation for Hernia.—Dr. Emory Lanphear (*Medical and Surgical Monitor*, May 15th) describes, in a paper read before the Academy of Medical and Surgical Sciences, a new operation devised by him to avoid the atrophy of the testicle which is noted to have occasionally followed Bassini's operation, and the tendency to recurrence which at times follows on the Czerny and Macewen methods. He says:

"A large flap is turned back, exposing the hernial sac and the inguinal canal in their entirety. The sac is then carefully dissected out, opened, and the contents reduced. At this stage the opening into the abdomen is closed with gauze and the spermatic cord and testicle lifted out of their natural position and enveloped in iodoform gauze. From the hernial sac (parietal peritoneum) there is now made a pouch or artificial tunica vaginalis testis, into which the testicle and cord are passed and inclosed with catgut sutures in such a way that not too much pressure is possible upon the cord; the whole is then pushed into the abdominal cavity and anchored by a few catgut sutures. The cut in the peritoneum is next closed; next the opening into the scrotum sutured; then each muscular layer of the abdominal wall carefully sutured, completely obliterating the canal—just as is done in operating for inguinal hernia in the female.

"That the ultimate fate of the buried testicle may be atrophy, the author can not dispute, as no opportunity has yet presented for post-mortem examination; that it is possible he can not deny. From a surgical standpoint, the chief objection to this operation is that a suppurative orchitis, or epididymitis might necessitate abdominal section; but suppurative inflammation of these structures is so comparatively rare that this danger, he thinks, can scarcely outweigh the advantages to be gained. So far, only the most gratifying results have been noted in the three cases thus operated on."

Acute Diffuse Gonococcal Peritonitis.—Dr. Harvey W. Cushing (*Bulletin of the Johns Hopkins Hospital*, May) thus concludes a very interesting paper containing the records of two cases operated upon: 1. The gonococcus is capable of causing a specific infectious disease—namely, gonorrhoea—and at the same time other and less specific pathological conditions. 2. There is experimental proof that in certain small animals the gonococcus can set up acute alterations in the peritoneum homologous with the acute septic serositis in man, but differing from these in their tendency to rapid and spontaneous healing. 3. Hitherto there has been wanting conclusive proof that in the peritonitides attendant upon gonorrhoea occurring in women, the gonococcus was solely or chiefly concerned. The inflammations had been variously regarded as mixed infections and chemical inflammations. 4. The cases reported in this paper bring for the first time convincing evidence of the existence of a diffuse, general inflammation of the abdominal cavity caused by the gonococcus. 5. It has been recognized that extension of the gonorrhoeal infection from the genital organs to the peritoneum may occur in the puerperal state; a similar sequel is shown to be possible during menstruation. 6.

Such ascending forms of gonorrhœa doubtless under ordinary circumstances remain localized in the pelvis, and rarely demand surgical investigation in the acute stage. 7. A general involvement of the peritonæum, such as occurred in the two cases given, must either be rare or unrecognized, and may depend upon some especially receptive condition of the serosa or virulence of the organism. 8. The peritonæum is not more immune than are the pericardium or endocardium to gonococcal infection, and, being more exposed, suffers more commonly in females, although the relatively benign course of the disease makes it a rare condition to come to the attention of the surgeon in the acute stages.

Stypticin in the Treatment of Uterine Hæmorrhage and Dysmenorrhœa.—At a recent meeting of the Munich Society of Gynecology and Obstetrics (*Centralblatt für Gynäkologie*, April 23d) Dr. Nassauer reported his continued experience with stypticin. It does not act upon the muscular structure of the uterus, like ergotine, he says, but upon the vasomotor nerves of the genital tract. It is useful in all uterine hæmorrhages not accompanied by some gross lesion of the uterine mucous membrane, but it is of no use in fungous endometritis until curetting has been employed, or in hæmorrhage after labor or abortion until all remnants of the ovum have been removed. In bleeding due to myoma it is effective only when the mucous membrane is intact, although it strikingly mitigates the pains of the menstrual periods or does away with them altogether. It is efficient against hæmorrhages caused by tumors of the annexa or by inflammation or congestion and against those of chlorosis and phthisis, as well as those of the climacteric. To secure its immediate action, three grains should be injected deep into the gluteal muscles; internally, of Mereh's tablets should be given every two hours, but not more than eight in twenty-four hours. In painful and profuse menstruation, it allays the pain while it moderates the flow.

A Mysterious Epidemic.—According to the *Medical and Surgical Review of Reviews* for May, a mysterious epidemic is reported to have broken out in the Hungarian village of Jas-bratbask, where the whole of the population are suffering from a peculiar disease. Out of five hundred inhabitants it is said that three hundred have already died. The attacks are accompanied by profuse hæmorrhages and violent mania. The origin of the disease has not yet been determined. Medical men sent from Budapest state that the disease is of a type hitherto unknown. A committee of medical experts has been sent from Vienna to make investigations.

American Gift to an English University. From the *British Medical Journal* for May 20th we learn that less than a year ago, at a meeting held in Birmingham, the scheme for a new midland university, to be called the University of Birmingham, was started. Mr. Chamberlain, in his speech, alluded on that occasion, and the promoters aimed at £250,000 as a minimum to endow the university. Such a sum was then thought to be many to be unattainable. But in less than twelve months the sum has been nearly all promised, and the committee now only require about £10,000 to enable the endowment fund a quarter of a million. Some few weeks ago an anonymous donor made the generous offer of £25,000 through Mr. Chamberlain on the condition

that the rest of the £250,000 was subscribed. This same donor, who still desires to remain anonymous, has during last week increased his offer to £37,000, made under the same conditions. At the same time Mr. Chamberlain announced the receipt of a letter from Mr. Andrew Carnegie, the American millionaire, in which he offered to give no less a sum than £50,000 toward the same object and under the same conditions. In his letter to Mr. Chamberlain Mr. Carnegie says: "If I were in your place I should recognize the futility of trying to rival Oxford and Cambridge, which, even if possible, would be useless. These twin seats of learning have their mission and fulfill it; but Birmingham should make the scientific the principal department, the classical subsidiary. If Birmingham were to adopt the policy suggested, taking our Cornell University as its model . . . and give degrees in science as in classics, I should be delighted to contribute the last £50,000 of the sum you have set out to raise to establish a scientific department. . . . Let this gift, therefore, be considered as only a slight acknowledgment of a debt which Pittsburgh, the greatest beneficiary of your steel inventions, can never hope to repay."

Public Bacteriological Laboratories for France.—From the *Medical and Surgical Review of Reviews* for May we learn that M. Emile Dubois has submitted to the Chamber of Deputies a proposal for the establishment in every department, at the public cost, of one or more bacteriological laboratories for the conduct of research with a view to the prevention of contagious diseases in general and tuberculosis in particular. It is but fitting, says the *Review*, that France, the native country of Pasteur, should take a leading position in the development of the science of bacteriology.

Precocious Sexual Maturity in a Newborn Infant.—Dr. A. Macabe Dallas, of Texore, Assam, records (*Indian Medical Record*, May 3d) a peculiar freak of Nature, or precocious maturity. In her first accouchement a lady gave birth to a male child, well developed and lean, the pubes being fully covered with hair about one eighth inch long. There was an unusually large penis, with complete absence of the foreskin. The glans was exposed and the surroundings had the appearance of a very neatly performed operation for circumcision, which it might prove difficult in later life to distinguish from that due to operative measures.

Another Christian-Science Trial. From the *Buffalo Medical Journal* for June we learn that a Mr. and Mrs. Saunders, living at Fort Porter, had a sick child seven years old who died on May 23d. When he was moribund, Dr. Walter D. McCaw, post-surgeon, was called in, but refused to certify to the cause of death and reported the case to the coroner. The next day a post mortem which showed the child to be afflicted with double pneumonia. It was learned that Mr. and Mrs. Kinter, Christian Science readers, had been "treating" the child, and the arrest of the case and the coroners followed. The evidence seems to show that, although Dr. McCaw, post-surgeon, and Dr. Norman W. Wilson, assistant surgeon, were called in to treat the case, they had not been called.

The district attorney, J. P. Cooney, conducting the prosecution, and Dr. McCaw with Cooney as his assistant, Mr. Brown, of Mr. Frank C. Beck's representation the Erie County Medical Society. Dr. W. L.

ham H. Heath is associated with the prosecution as medical expert. The entire moral, social, and financial force of the Christian Scientists has been thrown into the fight, which promises to be a long one.

Climate and Alcohol.—It is generally believed that the consumption of alcohol, especially in concentrated forms, is greatest in cold climates, and that its effects are there less harmful, owing to more rapid oxidation and the more active life of the natives, while the neglect to reduce the amount of alcohol in warmer regions is considered one of the chief causes of disease among Europeans in the tropics. The researches of Dr. Sikorsky, of Kief, as summarized in the *Semaine médicale*, seem to show that this is far from the truth. His country is admirably suited for such an investigation, for over a vast extent of latitude from the White Sea to the Caucasus the Russian peasant has for generations been testing the effects of his favorite solution of alcohol (*vodka*) with a vigor and persistence worthy of a martyr of science. According to official statistics, the north Russian drinks from 2.16 to 3.07 litres absolute alcohol per annum, while his brother in the south imbibes no less than 3.5 to 4.8 litres. Yet the deaths from alcoholism show a regular increase northward, being 15 to 22 to the million in south, 40 in the centre, and 70 to 110 in north Russia. Moreover, there is a marked increase of such deaths in specially cold years. Dr. Sikorsky concludes that cold greatly increases, even to threefold, the toxicity of alcohol, which, as is well known, so far from increasing bodily temperature, acts as a decided antithermic by paralyzing the peripheral vessels and diminishing organic metabolism.—*Revue scientifique* No. 10; abstract in *Janus*, May and June.

Venereal Disease and Divorce.—We gather from an article in the *Medical World* for June that the Paris court of appeals has decided that the fact of marrying while suffering from any venereal disease is sufficient cause alone on which to grant a divorce.

The Cause of the Healing of Tuberculous Peritonitis after Laparotomy.—Hildebrandt (*Münchener medizinische Wochenschrift*, 1898, Nos. 51 and 52; *American Journal of the Medical Sciences*, June) concludes as the result of extended investigation and experiments that the venous hyperemia, which lasts for days after laparotomy, is the important factor in the healing of tuberculous peritonitis after that operation.

The Sanitation of the Principality of Monaco.—According to the *British Medical Journal* for May 27th, Dr. Vivant, of Monte Carlo, in a communication read to the Société de médecine publique et d'hygiène professionnelle de France, summarizes the progress in public sanitation in the principality of Monaco during the last ten years. He deals with the subject under five heads: 1. Sanitary Legislation: This includes notification of infectious diseases, among which are reckoned pulmonary phthisis and tuberculosis in all forms, and strict regulations for the isolation and disinfection of houses and clothing of patients. 2. Drainage: The sewerage systems in the districts of Monaco, Monte Carlo, Le Moulin, and La Condamine are fully explained. 3. Water Supply: This is derived from three sources; chemical analysis of the water from each showed it to contain only a minimum amount of organic matter; and bacteriological examination specially made for the *Bacillus typhosus* and *Bacillus coli com-*

munis showed the absence of pathogenic organisms. 4. Meat Inspection: All meat killed at the abattoirs or imported into the principality is subject to strict inspection by veterinary experts. 5. The author refers also to the installation of the electric light and the electric tramways, and the appointment of a commission to supervise the erection of all new houses, so that plenty of air and sunlight is provided for. He remarks, in conclusion, on the rarity of cancer, pulmonary phthisis, and osseous and articular tuberculosis in the native born.

The International Tuberculosis Congress was formally opened on Wednesday, May 21th, in the chamber of the Reichstag in Berlin. The American representatives were Dr. de Schweinitz, Dr. A. J. Banker, of Columbus, Indiana, and Dr. John Kolmer, of Indianapolis.

The Crusade against the Public Spitting Nuisance.—In a letter to the *Suburban News*, of Hyde Park, Ohio, for June 10th, Dr. John Lewin McLeish, the health officer, enforces the well-known sanitary appeals for public co-operation in stopping this filthy nuisance with the following cogent remarks on the æsthetic side of the question:

"Complaints from various ladies of the village have been made to me of the foul, dirty, nasty agglomeration of mucus and tobacco expectoration upon our sidewalks, and in particular upon the public corners. As long as I am health officer this is going to be stopped, if we have to appoint a sanitary policeman for every corner in the village and for every offender. It should be only necessary to appeal to the sense of common decency and gentility of the offenders to abate the mawkish nuisance, for such it is, and this is the main intent of the regulation suggested.

"Expectoration is a habit, foul, unnecessary, uncleanly, and disgusting, and by the exercise of a little will power the offenders will be surprised to see how easily the incubus can be shaken off. Gentlemen do not find it necessary to go hawking and spitting around the drawing rooms or salons of their lady acquaintances, and they should not find it necessary to befoul the sidewalks and street corners, over which so many of their lady friends and relatives have to pass. An anti-expectoration campaign is an initial *sine qua non* toward the establishment of a first-class state of public health, and when this low, common nuisance is abated, as it is most certainly going to be in Hyde Park, other amendments will be suggested which, it is hoped, will make our classic suburb, of which we are justly proud, a model of sanitary perfection.

"Of course, if the expectorating gentlemen prefer to see the gentler sex swimming in mucus and tobacco spit upon the street corners, and if they have no objection to the increased expenditure for ladies' skirts and dress goods entailed, we will settle down contentedly in our spit-puttering little Venice, and, when it becomes necessary, invest in canoes.

"But if there is any efficacy in a sanitary policeman, a good club, and a wise squire, spitting in Hyde Park has got to go."

Death of Dr. Norman Kerr.—The death is announced as having occurred in London on May 31st of Dr. Norman Kerr, well known as an enthusiastic and able advocate of the cause of total abstinence in relation to alcohol.

Original Communications.

SOME CRITICAL AND DESULTORY REMARKS
ON RECENT LARYNGOLOGICAL AND
RHINOLOGICAL LITERATURE.

By JONATHAN WRIGHT, M.D.

(Ninth Paper.)

TUBERCULOSIS.

OF late years the endeavor to find in the laboratory an agent which could be introduced into the human organism to destroy the tubercle bacillus or its toxins has lost much of the impetus furnished by faith in the scientific spirit which for many years apparently animated workers in the biological laboratories of Germany. Recent incidents in the manufacture of the diphtheria antitoxine, and still more recently of "tubercle antitoxine," have more clearly indicated the commercialism rampant in quarters where we had long grown accustomed to look for truth only. There was a time when it was the proud boast of all scientific men, and it is still the pride of many, that their ideas, their work, and their methods were at the service of any honest fellow-worker. We hear now of closed doors in the laboratory, and, what is still worse, we hear of the necessity of closing them against the thief who filches the ideas of others and parades them as his own. These are the severest blows medical science has received, in our generation at least. The physician of the soul may ply his trade successfully, perhaps at a high salary; but the seeker for truth easily becomes merely the seeker for glory and gold when he lays aside either self-abnegation or self-respect. The very essence of the scientific spirit is annihilated at once by the intrusion of the selfish spirit of commercialism.

It may not be that the failure to discover an antitoxine or a bactericide for the tubercle bacillus in the human organism is to be ascribed entirely to the baleful tendencies which we can not but recognize in the domain of serotherapy. After our study of the therapeutic results of Koch's tuberculin; after the bright hopes which he professed for his various modifications of it; after the sweeping successes alleged for Maragliano's serum; after the more severe calls upon our credulity by the flaming announcements of pseudo-scientists, whose reputations are apparently only revered by the daily press; after it has become apparent that all these things are sinking into the oblivion which hides the myriad curatives of consumption, we are, I am sure, almost ready to believe that such an agent is not discovered because it does not exist. We are still more ready to infer this after reading the recent article by Dr. Trudeau and Dr. Baldwin.* They detail long, laborious, and carefully

varied experiments made with the view of obtaining some immunizing serum which could be used with some hope of success in the therapy of tuberculosis; but their efforts, which were supported by their long experience both in experimental and clinical work, have, as they admit, been entirely unsuccessful, and, while they do not abandon hope of a method being eventually discovered by which immunity to and successful treatment of tuberculosis may be attained, such a result is certainly not now in sight. The sum total of results thus far attained, so far as the practical application of them is concerned, is found in the diagnostic value of tuberculin for the detection of bovine tuberculosis. This is of very great value, and is, of course, worth all the labor and all the disappointment of the hopes which sprang up in connection with its discovery. Dr. Lydia Rabinowitch* has demonstrated the presence of the tubercle bacillus in specimens of market butter coming from a prominent butter merchant of Berlin. We have previous experiments recorded which induce us to believe that this is very exceptional. It can not be too often insisted upon that any given quantity of milk or butter may contain enough tubercle bacilli to kill guinea-pigs and still not contain enough to affect the human infant. This is a point which is as open to conjecture in one direction as the other. Although they say it takes from eight to thirty tubercle bacilli to infect a guinea-pig, there are no data upon which we can base an idea of the requisite minimum dose of the tubercle bacillus for the production of human tuberculosis. The late Dr. Kanthack, together with Dr. Sladen, had, before the death of the former, begun a series of investigations into the relation of the milk supply of Cambridge, England, to tuberculosis. In their paper,† which is merely an introduction to the projected work, their investigations show that over half the dairies supplying the town do so with milk in which the tubercle bacillus can be demonstrated. It is greatly to be regretted that any such work should be interrupted, and especially by the death of the distinguished pathologist who had undertaken it. It is, of course, impossible to say how the causal relation between the two phenomena, tubercle bacilli in the milk and tuberculosis in those who drank it, was to be demonstrated, but presumably through charts showing the coincidence of the two phenomena. Directly connected with this method of the invasion of the tubercle bacillus into the body must be studied the question of the paths which it traverses from the alimentary canal to the point where it causes the formation of tubercle. If we could suppose that tuberculosis of the respiratory organs arose from infection carried by the inspired air, and that tubercle elsewhere comes from the bacilli entering through the alimentary canal, the problem would seem simple, but a very little study of the question

* *American Journal of the Medical Sciences*, December, 1898, and January, 1899.

* *Lancet*, March 11, 1899.

† *Lancet*, January 14, 1899.

soon convinces us that this assumption is not warranted.

It will be remembered that Cornet, in the series of papers which he published ten years ago, showed that dust in the rooms of persons suffering from phthisis pulmonalis contained tubercle bacilli in large numbers. He also showed that this apparently was due to the pulverization of the dried sputum from such patients. He made, however, the comforting statement that the cough of phthisis patients did not spray tubercle bacilli into the air, because bacteria can not arise from the moist surface of the mucous membranes. Bacteriologists not only confirmed experimentally Cornet's observations in regard to the dust, but they reiterated his statements in regard to the tenacity with which bacilli cling to damp surfaces. I am sure that other laryngologists besides myself placed little dependence upon the latter assertions. It is one of the tricks of the laryngologist's trade, which the novice must learn early in his training, to dodge the globe of mucus as it is hurtled through the air from the gaping glottis of his patient. The knowledge that these viscid drops from a tuberculous lung are apt to contain bacilli always adds an extra agility to his movements. A recent paper of B. Fraenkel* reviews the work of Pflügge,† who has shown conclusively that phthisical patients *do* in the act of coughing, sneezing, clearing the throat, etc., spray tubercle bacilli into the air, and that in all probability this is the origin of many of the tubercle bacilli in dust. While this may be the origin of many of the tubercle bacilli in the dust, such numbers as could be expelled from the mouth in this way must, of course, be insignificant in comparison with the numbers expelled voluntarily in the profuse purulent expectoration of phthisical patients. It is a significant fact that in spite of the constant exposure of laryngologists to such contagion in their daily examination of the upper air-passages of tuberculous patients, no notable preponderance of tuberculous disease among them has been recorded. This is one of many practical observations which has convinced us that the majority of individuals are immune to ordinary doses of the tubercle bacillus accidentally taken in, and yet there are some individuals who are apparently infected by the smallest of such doses. It requires but very little reflection to perceive in this view of the case how important a factor in the aetiology is this individual index, but the fact must never be lost sight of that this individual immunity varies from time to time, and even that it is quite possible that such a dose may be taken in as would overcome the strongest systemic resistance. Fraenkel says that he has induced a large number of his phthisis patients to wear over their mouths a device for filtering the expired air, and in this way protecting those with whom they associate. In some instances he says patients may be induced to

do this under the delusion suggested to them by their medical attendant that the odoriferous medication with which the filtering cloth may be saturated is efficacious when continuously breathed in. Doubtless there are plenty of credulous patients to be found on whom this deception could be practised, but I am happy in the belief that there are not enough medical men in existence who would so far forget their own dignity and that of their profession as to make this suggestion of any value in checking the ravages of tuberculosis; while, on the other hand, I doubt if any other means could be adopted to make phthisical patients generally use this altruistic device.

The behavior of the larynx toward tuberculous infection has long been an interesting puzzle to laryngologists. I have long believed that its careful study would elicit important hints as to the mode of tuberculous infection and as to the means by which tubercle is disseminated throughout the body. One very great stumbling-block in the discussion of the means by which the larynx becomes tuberculous is contained in the terms of the problem itself as usually expressed: "What is the cause of tuberculous laryngitis?" It would be better to put the question thus: "Why is it that the larynx usually escapes infection with the tubercle bacillus?" Whether we suppose the tubercle bacillus to enter beneath the epithelium in the fauces or to pass downward with the air and secretions to the alveoli of the lungs, or whether it enters the system through the intestinal tract and is carried to the periphery by the blood or the lymph channels—whichever of these methods of invasion we believe to be the usual one, the problem which confronts us is, why the lungs are invaded so much more frequently than the larynx. If the infection enters at the fauces, or if it is carried in the inspired air, surely the larynx is more exposed to contagion than the pulmonary parenchyma. Moreover, when the latter has become affected, tuberculous sputum from a melting lung is dashed over the laryngeal mucous membrane by a rasping cough, and yet a very small percentage of cases of pulmonary phthisis acquire a laryngeal lesion before they die, and this small percentage is still further reduced if we rule out the cases in which the larynx breaks down in the last stages of the disease. Krieg has lately* analyzed seven hundred cases of tuberculous laryngitis coming under his observation, with the view of discovering the bearing such an analysis may have upon the question of the method of the tuberculous infection of the larynx. The results of his observations are summed up as follows:

"1. Among the seven hundred cases of tuberculous laryngitis are two hundred and seventy-five, or 39.3 per cent., unilateral, and four hundred and twenty-five, or 60.7 per cent., not unilateral. The unilateral cases appear then not to be at all unusual—as, for instance, Heinze assumes.

* *Berliner Klinische Wochenschrift*, No. 2, 1909.

† *Zeitschrift f. Hygiene*, Band xvi, S. 185.

* *Archiv für Laryngologie*, Band viii, Heft 3.

"2. Of the two hundred and seventy-five unilateral cases, two hundred and fifty-two correspond with the affected lung, or 91.6 per cent., while only twenty-three, or 8.4 per cent., do not correspond. Those that do correspond are therefore the vast majority of the cases.

"3. Of the seven hundred cases of laryngeal tuberculosis there are, therefore, two hundred and fifty-two, or thirty-six per cent., both unilateral and corresponding to the lung lesion."

As Krieg says, these and similar statistics, if reliable, are hard to explain on any hypothesis but that of propagation through the lymph channels. There should be no preponderance of infection on one side or the other if the infection occurred either primarily through the inspired air, or secondarily through the sputum coughed up from below. If, on the other hand, the bacillus enters beneath the epithelium of the fauces and finds its way into the cervical lymph channels, or if it enters by the gastro-intestinal tract primarily, and so gets into the lymphatics, or if it starts from the already infected lung by the way of the lymph channels, then we should naturally expect the pulmonary and laryngeal lesion to be on the same side. It is evident also that the blood-vessels would not be expected to produce this coincidence. It will be seen also that these statistics have a wider bearing than that which applies simply to the method of the secondary laryngeal involvement, for they affect the whole question both from the purely pathological standpoint and from the much more important standpoint of personal hygiene and general sanitation. But are the facts on which such statistics are based to be unhesitatingly accepted? What laryngologist is so expert that he can be sure from the picture in his mirror that the lesion is confined to one side of the larynx, or even that the surface manifestations of tuberculosis are confined to one side? The laryngoscope, even in the most skilled hands, is far from being an instrument of such precision. Even direct inspection of the surface after death furnishes no criterion of where the tubercle began or how far the microscope will show it has extended. On the other hand, what diagnostician is so acute as to be sure, even if he is so presumptuous as to assert, from auscultatory signs, that only one lung is involved? How is the diagnostician to form an opinion, trustworthy enough for such statistics as these, as to the condition of the bronchial glands at the base of the lungs? Anatomists may be able to tell us why the lymph channels prefer to deposit the germ at the level of the vocal cords, for at this situation tuberculous disease of the larynx usually first manifests itself, rather than at the bifurcation of the trachea or in the pharynx, but such an explanation at least has never come under my notice.

Nevertheless, this argument of Krieg is based on a large enough number of observations, if unbiased, to exclude casual errors. It is, moreover, supported by the difficulty we have in understanding how tubercle bacilli

get into the lungs themselves in any other way. The inspired air by the time it reaches even the larynx has had nearly all the germs filtered out of it, while it is only the residual air and not the tidal air at all which ever comes in contact with the peripheral twigs and leaves of the respiratory tree. Furthermore, primary tuberculous laryngitis is so rare that it has been confidently though wrongly, asserted never to exist. Were infection brought about by the germs in the tidal air in the larynx, it is hard to see why tuberculosis of the larynx should be so rarely observed without a well-marked lung lesion.

If we have long been in doubt as to tubercle bacilli reaching the lungs in the tidal air, post-mortem examinations have cast considerable doubts upon infection being frequent from the alimentary canal below the esophagus. Of late, various investigations have gone to show that in infants, contrary to former belief, thoracic tuberculosis is more common than abdominal, and that even children dying of pulmonary consumption, although they almost constantly swallow their sputum, do not by any means always present on autopsy evidence of lesions in the abdominal viscera. This is especially the case in infants under one year of age—the very age at which they are nourished by milk. Clinicians are beginning to declare that many cases diagnosed as tuberculosis of the bowels among the children of the poor are really only cases of marasmus from malnutrition, many of them promptly recovering when brought under proper dietetic and hygienic conditions.

There are, therefore, good reasons for believing that the tubercle bacillus enters the human organism before it reaches either the lungs or the stomach, in at least a large number, if not in the majority, of the cases. If this is the rule, and not the exception, it would explain many phenomena, but not by any means all of them. Tubercle bacilli may be deposited in the nose, nasopharynx, and oropharynx by the inspired air, or in the oropharynx and esophagus by the food, and thus passing through the epithelium to the lymph channels may be distributed to the various localities where they produce tubercle. It must not be forgotten, in considering certain localities, from clinical experience, as especially liable to the deposit of tubercle, that post-mortem examinations show that other localities which are closed to clinical investigation are quite as frequently the site of tuberculous disease; but under the supposition that the bacillus passes through the epithelium in the mouth or its annexa, we are at once reminded that these are especially the localities which, while perfectly accessible to examination, are strikingly free from primary tuberculosis. Shall we assume that the tubercle bacillus must usually first acquire some virulent property from a lymph node before it can cause tubercle? Can we gather any hint of this from the difference in the clinical behavior of lupus and other forms of tuberculosis?

The most reliable subjective symptom of pulmonary tuberculosis is the spitting of blood. It does not re-

quire a great deal of clinical experience before one gets into the habit of mind which is, perhaps, not entirely scientific in the presence of any case with this history. The presumptive diagnosis is at once phthisis pulmonalis, and our subsequent investigations are made with that bias in mind. When the laryngologist by his examination has excluded the possible sources of hemorrhage which lie above the rima glottidis, this mental bias is still more firmly established; but evidently he is in danger of error.

Professor Massei, the eminent laryngologist of Naples, describes* a class of cases to which he gives the name of chronic hemorrhagic tracheal catarrh. These patients occasionally spit small quantities of blood. They have a dry cough and present the ordinary picture of incipient pulmonary tuberculosis, but deep, brilliant illumination of the trachea discloses engorged blood-vessels in a chronically inflamed mucous membrane. In the absence of tubercle bacilli and of positive physical signs in the lungs this is sufficient to establish the diagnosis. So far as my own experience goes, I should think these cases must be very rare, as I have no recollection of ever having seen a case of spitting of blood, which I was sure came from below the glottis, in whose sputum I did not eventually find the tubercle bacillus. In very many cases, however, a satisfactory view of the trachea can not be had with the laryngoscope. We usually have to be satisfied with a more or less incomplete picture of the tracheal mucosa. It is therefore very possible that cases such as Massei has described may go undetected. The condition of the trachea no doubt may frequently explain the puzzling coughs which we have to treat, but the absence of physical signs over the chest wall is seldom conclusive evidence of the non-involvement of the lung substance in such cases. While, therefore, we should wrong our patients by regarding blood spitting, in the absence of other signs, as satisfactory evidence, of tuberculosis of the lungs, we should be much more apt to wrong them by not keeping in mind that diagnosis as a probability in any given case. Notwithstanding the fact that the tubercle bacillus, when found in the sputum, absolutely establishes the diagnosis, and its persistent absence renders the diagnosis of tuberculosis very improbable, and although this has been recognized now for more than fifteen years, a large number of practitioners fail to examine, or have examined, the sputum of patients, not only when other signs point to phthisis pulmonalis, but even when the nature of the case is not clear. This is not only true of hospital practice, but is also true of private practice. I have known of several instances in which life has been lost through mistakes which need not have been made had the rule been adhered to of always examining the sputum in cases of laryngitis accompanying chronic pulmonary troubles. I am sorry to be obliged

to confess that I have myself not been free from blame in some of these cases. I refer to cases of laryngeal and pulmonary syphilis dying from the want of the iodide of potassium and mercury. The absence of the tubercle bacillus from the sputum is regarded as a sign of little value as to the freedom of the lungs from tuberculous disease. While this is doubtless true, it is important that laryngologists should beware of persisting in a preconceived diagnosis of tuberculous laryngitis when the tubercle bacillus can not be found in the sputum. Neither should they cling to the diagnosis of tubercle because physical signs intimate the presence of a concomitant pulmonary lesion. As a rule, almost without exception, when a phthisical patient is affected with tuberculous laryngitis the lung lesion has gone so far that tubercle bacilli on careful examination are always found in the sputum. Pulmonary syphilis will cause the same physical signs as pulmonary tuberculosis.

In this connection attention may be drawn to the report of a so-called case of primary laryngeal tuberculosis reported by Trifelletti,* since it illustrates another phase of mistaken differential diagnosis in these cases, and also throws some light upon the statistics of cure of tubercular laryngitis. It offers a marked contrast to some of the carefully reported cases which Dr. Gleitsmann has shown at the Academy of Medicine. Trifelletti's case was that of a man who had a marked history of previous syphilitic lesions. In his larynx he presented a condition which the reporter declares bore every clinical appearance of tertiary syphilis, and he gave no definite signs of pulmonary involvement. He received antisyphilitic treatment, and the laryngeal lesion improved markedly up to a certain point, when it remained stationary for a time, and then slowly became worse. Examination of the sputum did not show tubercle bacilli. Examination of the tissues also failed to reveal them, but showed small round-celled infiltration with a number of giant cells. Some of the tissue was used to inoculate a rabbit, but the results were negative. Surgical treatment of the laryngeal lesion brought about cicatrization and cure. Although, as said above, the presence of the tubercle bacillus was not demonstrated, although the clinical evidence of syphilis was perfectly clear, yet, on the strength of the finding of giant cells and the incomplete results of antisyphilitic medication, the diagnosis of a primary tuberculosis was made and the cure of laryngeal tuberculosis was attributed to surgical treatment. The actual occurrence of either of these events is one of the rarest phenomena known to medical science. As a matter of fact, on the other hand, it is not an uncommon thing at all, as Manasse has pointed out for the nose, to find large numbers of giant cells in the syphilitic lesions of the upper air-passages. So far, then, as the report of this case of primary tuberculosis of the larynx and of its cure by surgical means can be

* *Archivii ital. di laringologia*, Fasc. 1, 1898.

* *Archivii ital. di laringologia*, No. 1, 1898.

judged, the casual reader is warranted in regarding the writer's views of its nature as mistaken. With such a history, the demonstration of the tubercle bacillus is positively essential to the diagnosis of tuberculosis. One can not even admit the probability of a mixed infection or of the possibility of a tuberculous infection of a syphilitic lesion. Hansemann, in the *Berliner klinische Wochenschrift*, No. 2, 1898, has written a very good paper on secondary infection by the tubercle bacillus.

In his well-known opposition to the contentions of the high contagionists, he goes to what would appear to them extreme limits. He states that many cases of cheesy degeneration of the pulmonary parenchyma occur following repeated attacks of pneumonia, and that these areas of degeneration in many cases become only secondarily infected by the tubercle bacillus—that frequently many syphilitic lesions become secondarily infected by the tubercle bacillus. There have been many recent publications which tend to show that the general consensus of opinion is veering toward these conclusions, although many of us who have always been, even in the era of the *furor* of bacteriomania, low contagionists, will hesitate to believe that this is the usual sequence of events.

A PRIMARY POLYMORPHOUS-CELL SARCOMA OF THE NOSE.

WITH UNIVERSAL METASTASIS
AND FORMATION OF A FREE SARCOMATOUS MASS
IN THE RIGHT VENTRICULAR CAVITY

By ALFRED SCOTT WARTHIN, M. D., Ph. D.,
INSTRUCTOR IN PATHOLOGY, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICH.

THE reports of sarcoma of the nasal passages have multiplied to so great an extent during the last several years that the condition can no longer be looked upon as one of very rare occurrence. Bosworth, in 1889, had collected from the literature previous to that year reports of forty-one cases. In 1896 twenty-one cases were added to this list by Boylan, and I have been able to find in the literature since the latter's paper reports of twenty-seven additional cases. It is evident from this rapid increase of reported cases that sarcoma of the nose must occur with some degree of frequency.

The sarcomatous tumors described as being found in the nose present a wide variety in kind. Small and large round cell, spindle cell, lymphosarcoma, fibrosarcoma, myxosarcoma, osteosarcoma, osteoid sarcoma, angiosarcoma, myxosarcoma, alveolar sarcoma, and melanotic sarcoma have been reported as occurring in this region. The site of the tumor presents also a wide range. The turbinated and nasal bones, the perpendicular of these bones, the nasal cartilages, the cartilage of the mucosa of the nose, the blood vessels and connective tissue of the mucosa of the nose and nasopharynx have all given rise to sarcomata. In a number of cases an attempt has been made to prove their origin from con-

ditional polyp. The evidence upon this point, however, is very slight, and there is no proof of any close relation between a benign polyp and sarcoma. From the cases reported they would seem to be of independent origin. The nasal sarcoma, because of its location and the conditions of its growth, often presents a polypoid form, and in those cases in which a myxoma was thought to have become sarcomatous it is more probable that the so-called polyp was malignant from the beginning. The possibility of the development of a sarcoma in a benign polyp need not be denied, but in those cases where this change was thought to have taken place the microscopic evidence is either entirely wanting or insufficient.

The opinion is quite generally held in the older literature that sarcoma of the nasal passages is not so malignant as sarcoma occurring in other regions of the body. Bosworth concludes from the result of his study of forty-two cases that "sarcoma of the nose does not apparently present the same malignant tendencies as it does when found in other locations." Warren, in his *Surgical Pathology*, says: "The disease does not appear to show the same malignant tendencies in the nasal passages that it does in other localities." And Boylan, from the study of his twenty-one cases, is inclined to favor this opinion, since rapid recurrence took place after operation in the minority of cases, and in others there was a prolonged or permanent cure. From these points he concludes that the prognosis in nasal sarcoma is relatively favorable.

A study of the literature since Boylan's paper, however, leads to the conclusion that there is no justification for the assumption that sarcoma of the nasal passages is less malignant than in other regions. It is less malignant only in so far as it is in a situation where it may possibly be thoroughly removed. While many of the nasal sarcomata described have been of slow growth and slow recurrence, this is also true of sarcomata in other parts of the body. The slow growth of a sarcoma or carcinoma should never deceive us as to its possibilities of malignancy or lead us to delay in operative measures. Slow growing sarcomata of the nose have sometimes taken on an extraordinarily rapid growth just as in other part of the body. The possibility of a favorable prognosis in nasal sarcoma is based, therefore, purely upon the operative conditions, and not upon the character of the tumor.

The case which I present here is one of great value, first, in that it is a new addition to the list of sarcomata found in the nose; second, in that it is of its great malignancy; third, because of its great extent and interesting character of the metastasis; and the occurrence of a free sarcomatous mass in the right ventricular cavity. The history of the case is as follows:

Mr. J. F., aged thirty-one years, was admitted to the University Hospital on the 1st of April, 1897. He was a lumberman, born in a well-to-do executive family

history. Previous to the beginning of the present condition his health had been good. A year and a half before admission his right nostril became partially occluded. By blowing his nose with some violence he could force out large "scabby, flaky masses." This condition lasted for a year, when a vesicular eruption becoming pustular gradually spread over the right side of the nose, extending to the left. Three months before admission he had had a number of "polypoids" removed from his right nostril. The patient did not know whether a microscopic examination of these had been made, but was told that they were ordinary nasal polypi. From the treatment of the case it is evident that the operator had regarded them as benign growths, as when the patient entered the hospital no suspicion had been raised as to the malignant nature of his disease.

He had been under treatment with a number of physicians who had diagnosed his condition as eczema, syphilis, and lupus. He had no history of acquired syphilis, and under specific treatment his condition had grown steadily worse.

A month before admission he had noticed numbness over the left side of the nose, left cheek, upper lip, and forehead to the median line. Diplopia, left-sided ptosis, and dilatation of the left pupil soon followed.

On admission the general condition of the patient appeared fair. He complained of weakness, nervousness, insomnia, and of dull pain in his forehead. His appetite was poor, and bowels were constipated. He passed about one litre of urine daily, very highly colored, and with specific gravity of 1.034. His nostrils were completely occluded, his breathing being entirely by the mouth and very shallow in character. His nose was symmetrically enlarged; the skin covered with yellowish, opaque crusts, with scattered pustules. Around this and extending slightly into the skin of each cheek there was redness with firm induration. The nostrils were filled with grayish-red masses. There was no odor.

The sense of smell was entirely lost. There was complete anaesthesia over the distribution of the supraorbital and infraorbital branches of the fifth nerve. There was some atrophy of the muscles in this area. Ptosis of the left lid was present, with complete paralysis of the muscles of the left eyeball. Sight was diminished in the left eye. The retinal examination showed a marked degree of choked disk. The patient's mind was clear.

A clinical diagnosis was made of malignant tumor of the nose with secondaries at the base of the brain, involving the first, second, third, fourth, the first and second branches of the fifth motor fibres of the fifth and the sixth cranial nerves. The condition of the patient gradually became worse. No operation was attempted. On the 14th of May he had attacks of nausea and vomiting, followed by great disturbance of respiration and circulation. The extremities became oedematous, the patient sank into coma and died on the 17th of May. The necropsy was performed by me in the university laboratory of pathology four hours after the patient's death. The gross findings were as follows:

Section-praecord.—Body of medium height and slender build. The musculature good, slightly flabby. Fair amount of panniculus. No oedema. Skin sallow, nutrition fair. Marked hypostasis, amounting to cyanosis over the upper part of thorax, head, and back. Rigor mortis present in all muscles. Body heat present.

Head: Face cyanotic. There is a subcutaneous growth extending over the entire nose and a short distance into each cheek. The skin over this is thickened, rough, scaly,

with numerous minute vesicles. The nostrils are completely closed by masses of soft, grayish-red tissue. The growth does not extend into the mouth. Over the bridge of the nose there is a small ulcer covered with surgical dressings. The nasal bones and cartilage seem completely replaced by the growth.

Brain: A small, soft growth, of the size of a cherry, is found on the inner surface of the dura near the longitudinal sinus. The pia is congested; all of the sinuses are distended with fluid blood. The brain substance is hyperemic and oedematous. There is a large amount of clear fluid in the lateral ventricles, which are somewhat distended. The pineal body is replaced by a tumor nodule, of the size of a large cherry. Otherwise the brain seems normal. The hypophysis is replaced by a tumor growth. The left third nerve is surrounded by a thick mass of new growth which is partly colloid in appearance. The left Gasserian ganglion is greatly enlarged and completely surrounded by new growth. The nasal fossa is completely filled with a soft tumor mass, showing extensive mucous degeneration. This mass is directly continuous with tumor masses filling up the frontal sinus, the sphenomaxillary fossa, and with the mass in the nostrils. The left cavernous sinus is also filled with tumor tissue. All of these masses are very soft, homogeneous, and show myxomatous change. The right third nerve and Gasserian ganglion are normal.

The examination of mouth, larynx, and trachea is negative.

Thyroid enlarged, and shows colloid degeneration.

The main incision shows marked venous congestion everywhere. The tissues bleed freely. The muscles are red, moist, and soft. There is a moderate amount of abdominal fat. The position of the abdominal organs is normal. There is no fluid in the peritoneal cavity.

Diaphragm extends to the fourth intercostal space on the right, to the fifth interspace on the left.

No remains of the thymus are present. The mediastinal tissue contains a number of enlarged lymph glands.

Pericardium: The pericardium contains about one hundred cubic centimetres of cloudy fluid in which there are small flakes of fibrin. The surface of the pericardium is dull and clouded. There are no new growths in the pericardial layers.

Heart: Of about twice the normal size, and very irregular in shape. The surface is irregularly nodular, the nodules appearing yellowish as seen through the epicardium. They are elevated, firm, and do not show any umbilication. A thick ring of new growth extends around the auriculo-ventricular groove. On section the heart muscle is almost entirely replaced by homogeneous yellowish-white areas, contrasting strongly with the deep red of the remaining heart muscle. These areas project as rounded nodules into the cavities of the heart, and form the nodules seen on the surface beneath the epicardium.

Many of these areas are surrounded by a zone of hyperemia or hemorrhage. The centre of some of the nodules is soft, in others there is a colloid appearance. The endocardium appears unchanged, and in no place does it give any evidence of a breaking-through of the tumor. In the left ventricular cavity there is a large jelly clot with some fluid blood, and in the auricles and great vessels are large white clots. The right ventricle contains some fluid blood and a large firm mass, about the size and shape of a large English walnut. It is grayish-red in color, and has a ribbed and furrowed surface

suggesting the appearance of brain coral. Its surface presents no appearance of any previous union with the heart wall, nor can any evidence of such connection be found in the endocardium of the right heart.

Lungs: There are about five hundred cubic centimetres of turbid fluid in each pleural sac. The surfaces of the pleura are cloudy and are covered with numerous flakes of fibrin. All over the surfaces of both parietal and visceral pleura are scattered numerous small growths, varying in size, but for the most part of the size of a small pea. In the parietal pleura they are arranged in rows corresponding to the direction of the ribs. The right lung shows extreme congestion and oedema. There is a moderate anthracosis. Throughout its substance there are many small growths, most abundant about the bronchi and under the pleura. These tumors are soft, white, and perfectly homogeneous. The left lung presents a similar appearance, but shows fewer of the growths. There are several small deep-red areas in the lower lobe just under the pleura. These are triangular in shape, with their bases beneath the pleura.

Bronchial glands: These contain large masses of new growth. On section they are soft, white, and homogeneous, and show a colloid appearance in their central portions.

The examination of the thoracic vessels and œsophagus is negative.

Spleen enlarged, very soft, cyanotic. On its anterior margin near the deepest fissure are two cavernous tumors about the size of small hickory nuts. On section the pulp is deep red, very soft, flows readily. The follicles are not visible and the stroma is unchanged. There are a number of depressed areas, grayish-red in color, with deep-red borders, and of firm consistence.

Adrenals show no change.

Kidneys: Both enlarged and cyanotic. The fat capsule is rather thick. The fibrous capsule is not adherent, except in areas corresponding to small white nodules in the capsule. On section both kidneys present practically the same appearances. The cortex is increased in thickness, deep bluish-red, of increased consistence. The cut surface bleeds very freely. The glomeruli can not be made out. The pelvis is filled with large tumor masses extending up between the pyramids into the kidney substance, and also into the pyramids themselves. The new growth is very soft, white, homogeneous, and in many places myxomatous. The chief portion of the new growth seems to be in the cavity of the pelvis, which is greatly dilated. It is not adherent to the mucosa of the pelvis, as it can be easily separated from this, leaving the surface free and apparently unchanged. The growths extend out around the renal vessels into the retroperitoneal tissues. The retroperitoneal glands are replaced by large masses of new growth of the same character as described above. The ureters are dilated, the mucosa is thickened.

Bladder: The walls are thickened, and there is a small area of hyperæmia with fibrinous exudate on the posterior wall.

Genitals: The external genitals are apparently unchanged. The right testis is slightly enlarged. The body of the testis is replaced by tumor growth of the same nature as that described above. The left testis contains a growth of the size of a walnut. It is of the same character as that described above. The prostate is enlarged, but appears normal.

Intestines: Appendix normal. The mucosa of the small and large intestine is injected. In the serous coat

are several small nodules of new growth. The mesenteric glands contain also tumor nodules.

Stomach: On the floor of stomach about the middle of the greater curvature there is a round ulcer, of about the size of a dollar, with sharp clean edges, extending to the muscular coat. Near this are two irregular areas of infiltration of new growth in the mucosa and submucosa. They are flat and do not extend into the muscularis. On section they present the same appearance seen in all of the other tumor masses, and show a beginning central degeneration. In other parts of the mucosa there are small erosions with thickened bases and indurated edges.

Pancreas: The head of the pancreas is replaced by a large tumor mass. On section this shows the same appearance as seen elsewhere.

Liver: The size is about normal; the left lobe is very long and thin. On section, the surface is dark-red and cyanotic, and bleeds freely. In some areas there is a distinct nutmeg appearance; the connective tissue is somewhat increased. No growths can be perceived by the naked eye. The examination of the gall bladder and biliary passages is negative.

Lymph glands: The cervical glands on the left side contain large tumor masses.

Microscopical Examination.—An abundance of material was taken from all parts of the body and fixed in alcohol, mercuric bichloride, and Müller's fluid. Both paraffin and celloidin imbedding methods were employed, and the sections were stained with various stains, hamatoxylin and eosin and Van Gieson's method being most commonly used. The microscopical examination of the sections taken from the primary tumor and from the metastases revealed such a variety of pictures that at first sight it seemed impossible that the different growths could be of the same origin. A careful study of these, however, made plain the fact that the differences in appearance were due to differences in the age of the growths and to the conditions in the tissues where they were located.

Primary growth: Section taken from the periphery of the primary tumor in the nasal fossa and from the infiltration of the skin and subcutaneous tissue of the nose present the appearance of a small round-cell sarcoma. The mass of the structure is composed of small round, deeply staining cells; there is a very scanty reticulum, with numerous large and thin-walled blood-vessels lying in intimate contact with the cells. The deeper parts of the nasal tumor give varied pictures. There the cells for the greater part are not of the small, round-cell type, but are much larger and very irregular in shape. Division figures are very numerous, and many of the cells have large and very irregularly shaped nuclei possessing a great excess of chromatin. "Grape-cluster" nuclei are very common, and many giant cells are found. In these older parts of the growth there is a greater amount of intercellular substance than in the peripheral portions. The cells are separated by a clear, slightly refractive substance, which does not stain with eosin or acid fuchsin, but gives the reactions for mucin. In the fresh tumor the intercellular substance must have been fluid. As in these older parts of the growth the number of cells is not nearly so great as in the areas of more recent development, it is probable that the intercellular substance has arisen from the degeneration or solution of part of the cells. Support is given to this view by the fact that the central part of all the larger masses is filled with a similar mucoid substance, the cells having entirely disappeared. In the fresh tumor the areas present-

ed a colloid appearance, sometimes firm in consistence, at other times more watery. The posterior part of the nasal fossa was completely filled with this jellylike mucin. In many places these cystlike spaces are surrounded by a capsule of granulation tissue. It would seem that the tumor in its growth had reached a certain height in these areas, the cells had completely degenerated, and there had been an attempt at encapsulation. No typical mucous tissue was found in any part of the original tumor or in any of the metastases.

Dura: The small growth taken from the dura presents the appearance of a small round-cell sarcoma.

Pineal body: The growth here is polymorphous-celled and shows myxomatous degeneration in the central part. The peripheral portion has the appearance of a small round-cell sarcoma.

Hypophysis: This is almost entirely replaced by a central tumor mass which is of the type of a polymorphous-cell alveolar sarcoma. The central part shows a marked myxomatous change. Many giant cells are present here, and the irregularity in the size of the nuclei is very marked. In the periphery are nodules of small round cells.

Gasserian ganglion: The sections of the mass taken from the region of the left Gasserian ganglion show a beautiful picture of the infiltration of large nerve trunks and ganglion by sarcoma cells. There are many of the ganglion cells preserved, surrounded by small, round cells, from which they stand out in sharp contrast. They are swollen and granular, but their nuclei and nucleoli can be distinctly made out, and their nucleated capsules appear unchanged. The nerve fibres of the large nerve trunks are widely separated by tumor cells and in many places have a knotted, swollen appearance. In the sections stained by Van Gieson's method these knotted fibres have a greenish color. The tumor cells here, like those in the central portions of the primary growth, are very irregular in size and shape. There are many giant cells with large nuclei showing marked hyperchromatism. Many of the nuclei are star-shaped, others are ragged in outline. Caryomitotic and amitotic division forms are abundant. There are many ectatic blood-vessels. The central portion of the growth shows also a myxomatous change. Throughout the trunk of the left third nerve there is an infiltration of sarcoma cells. The colloid mass into which the third nerve passed is a cavity filled with a colloidlike mucin surrounded by a capsule of granulation tissue. Outside of this capsule the tumor cells are of more uniform size and there are not so many giant cells. The blood-vessels are very numerous and large.

Heart: The entire heart wall is infiltrated with tumor cells. The muscle in many areas is wholly replaced by nodules of polymorphous cells. The larger nodules show myxomatous change and in every way present an appearance similar to that of the original growth. The remaining muscle cells are greatly atrophied and are widely separated by small round cells. Many of the muscle fibres show simple and waxy necrosis. The entire endocardium is infiltrated with small round cells, and in one area in the right ventricular wall the tumor cells have broken through the endothelium and form a small flattened growth on the wall of the ventricular cavity. This could not be seen in the naked-eye examination.

The sections of the free mass in the right ventricular cavity show it to be of sarcomatous structure. There are many cells larger than leucocytes and possessing large vacuolated nuclei. A few giant cells are found, and

many cells with large, irregular, deeply-staining nuclei. The majority of the cells are of the small round variety. At one side of the mass there is a collection of red blood-cells and fibrin. A very scanty reticulum can be made out and a few small blood-vessels can be seen. The origin of the mass seems very evident after the microscopical study of the endocardium of the right ventricle. It is undoubtedly a polypoid nodule that, projecting from the endocardium, grew until it was too large to pass out of the ventricle, and then breaking loose continued to grow as a free body. The mass shows no necrosis or degeneration.

Lung and pleura: The small growths in the pleura are of the type of a small round-cell sarcoma. The larger ones show a polymorphous variety of cells and myxomatous degeneration. The small nodules throughout the lung consist of small round cells, the larger ones of polymorphous cells. There is hardly a blood-vessel throughout the lung that has not a circumvascular growth of sarcoma cells. Numerous emboli of sarcoma cells are found in the capillaries. In many of the smallest growths the cells are irregular in size and shape and show great excess of chromatin. The lung shows extreme oedema and congestion, and there are several hæmorrhagic infarcts and small areas of broncho-pneumonia. Many of the larger tumor nodules show a healing process and the formation of scar tissue in the central part of the nodule. This can be seen in all stages, from a beginning formation of granulation tissue around the myxomatous portion of the tumor to nodules made up of scar tissue alone.

Spleen: Small nodules of tumor cells are found throughout this organ. There are also a number of anæmic infarcts.

Liver: A number of small nodules of small round cells are found in the periportal connective tissue.

Kidneys: There is an acute degenerative nephritis present, and the greater part of both kidneys is replaced by masses of sarcomatous tissue of the same structure as described above. Many of the smaller nodules are made up of the polymorphous cell type.

Pancreas: The head of the pancreas is almost entirely replaced by a sarcomatous mass, which is made up chiefly of small round cells, but contains also many polymorphous cells.

Stomach: The base of the round ulcer and the flat infiltrations of the mucosa consist of nodules of sarcoma. The ulcer is apparently caused by the mucous degeneration of a large nodule projecting through the mucosa. The structure of these nodules in the wall of the stomach is the same as that found in the other tumors.

Intestine: The small nodules in the serosa are of the same type of sarcoma as that described above.

Testis: The tumors here present the appearance of a small round-cell sarcoma. Areas of mucous degeneration are abundant, and the blood-vessels are very numerous and ectatic.

Prostate: The prostate contains localized areas of small round cells.

Lymph glands: The cervical, peribronchial, mesenteric, and retroperitoneal lymph glands contain large nodules of polymorphous or small round-cell sarcoma. The majority of these show mucous degeneration.

Summary.—All of the growths are of the nature of sarcoma. The majority of the smaller nodules and the periphery of all the larger ones are made up of small, round, deeply-staining cells having but little intercellular substance and lying in intimate contact with the

blood-vessels. In the central part of all the larger nodules, and in some of the small ones, the cells are larger, polymorphous, and there is an increase in the intercellular substance, which is myxomatous in character. In many of the nodules the entire central part of the growth has undergone a mucous degeneration, and early stages of this degeneration are seen in all of the growths. The tumors are further characterized throughout by the number and size of the blood-vessels. From the structure of the growth the diagnosis of the tumor as a myxomatous polymorphous-celled sarcoma would seem most appropriate.

That the growth in the nasal fossa is the primary one there can be no reasonable doubt. The history of the case, the development of the symptoms, the size and structure of the nasal growth all support this view. The exact site of origin can not be determined. The patient affirmed that it appeared first in the right nostril upon the right side of the septum. Moreover, the relation of the sarcoma to the polyps stated to have been removed can not be settled in the absence of any definite microscopical evidence concerning their structure. The fact that the tumor everywhere shows a marked tendency to a mucous degeneration of its cells and the formation of a myxomatous intercellular substance might be taken as an evidence of an inherited tendency on the part of its cells tending to show a descent from a myxomatous polyp. This, unfortunately, will not admit of further confirmation.

The points of special interest in this case are the widespread metastases and the intracardiac growth. Secondaries were found in the dura, pineal body, hypophysis, cavernous sinus, lungs, pleura, heart, liver, spleen, kidneys, pancreas, stomach, intestines, peritoneum, testicles, prostate, and the cervical, bronchial, retroperitoneal, and mesenteric lymph glands. The richness of the growth in cellular elements, the scanty stroma, the numerous large thin-walled blood-vessels, the smallness and shape of the cells, all contributed to the facility of the rapid dissemination of the tumor. The numerous metastases throughout both venous and arterial systems are easily explained by the above-mentioned factors.

The free sarcomatous body in the right ventricular cavity forms the most important feature of the case. Intracardiac and intravenous growths are very rare both in carcinoma and sarcoma, but have been described in both, more frequently in the case of the latter. Kanthack* has described a case of carcinoma of the testis in which there was a metastatic mass upon the tricuspid valve extending through the auricle into the inferior vena cava and through the tricuspid orifice into the cavity of the right ventricle. The origin of this seemed to have been from an intravenous growth in the inferior vena cava, a fragment of which must have become separated and grafted upon the tricuspid valve, where it continued to grow.

The probable origin in my case is that suggested above—namely, the breaking loose of a polypoid nodule

from the endocardium, its retention in the ventricle, and its subsequent growth. Microscopically the endocardium was infiltrated with sarcoma cells, and in one place there was found the thin, flattened growth on the surface of the endocardium. This may have been the origin of the mass, or, on the other hand, it may have arisen from a primary embolus of tumor cells retained in the heart cavity. The numerous emboli of tumor cells found in the lung vessels and the hemorrhagic infarcts of the lung may have resulted from the breaking loose of portions of this intracardiac growth. The anemic infarcts in the spleen were also probably caused by emboli of sarcoma cells, as masses of these cells could be seen growing in dilated blood-spaces of this organ.

Another point of interest in the growth of this tumor is its tendency to self-healing. As mentioned above, this could be seen in all stages, from the beginning of the formation of a granulation-tissue capsule around the area of degeneration to completely formed nodules of scar tissue completely replacing the tumor.

HOW TO GIVE ANÆSTHETICS.*

By WILLIAM S. DEUTSCH, M. D.,

ST. LOUIS,

ANÆSTHETIST TO THE MISSOURI MEDICAL COLLEGE SURGICAL CLINIC,
DR. TUHOLSKÉ'S SURGICAL AND GYNÆCOLOGICAL HOSPITAL, ETC.

FROM the title of this paper it might be judged that I mean to pose as an instructor in the art of anæsthetization, or perhaps place myself on a higher level than the many physicians who are daily called upon to administer anæsthetics. This is not my object, but I mean only to present to you such facts and experiences as appeal to me as I now look back over my past eight years' work in this field.

I believe that those practitioners who administer anæsthetics will agree with me that they have derived little or no benefit from reference or text books on this subject, but have been compelled, like myself, to study and learn the art of anæsthetization in the hard school of experience.

Ether and chloroform are the only drugs I have been called upon to administer. I have given ether seven hundred and eighty times and chloroform two hundred and ninety-five times, making a total of a thousand and seventy-five anæsthesias, and, I am glad to be able to report, without one death. These anæsthetics were not used in selected cases, but were administered in the charity wards of city institutions, college dispensaries, private hospitals, and private practice.

I believe that the art of administering anæsthetics can be learned only by continual practice. Books and the experiences of others count for little, for the prime prerequisites for the making of a successful anæsthetist are self-confidence, the knowledge of the dangers that might arise during the administration, and ability to combat them when they occur.

What surgeon or physician does not appreciate what a sense of responsibility and what a bugbear the anæsthesia is to him, and how different does he feel when a stranger is giving the anæsthetic! How often is the operation so small that it really is of secondary importance as compared with the dangers of anæsthesia! I believe, therefore, that the time should be close at hand when in this country more physicians will make a study of and follow as a specialty the administration of anæsthetics; and, furthermore, that this subject will be

taught separately and thoroughly in our medical schools.

There are some underlying rules and principles which should govern every administrator of anæsthetics, and they are the following:

He must give the anæsthetic, and absolutely and positively do nothing else. By this I mean he must not allow his whole attention or any part of it to be taken away for a minute from the patient under the anæsthetic. Neither the interesting operation, the talkative physicians around, nor a fascinating nurse should for one second engage his attention, for in that time his patient might die—I care not how well skilled he may believe himself to be, or how certain he feels that he has a healthy patient under the anæsthetic, for it has been under exactly such circumstances that a death from anæsthesia has occurred.

I have not any doubt but that death will occasionally occur from an anæsthetic, even when administered by men who have had experience in the art, from causes over which they have no control, and it therefore behooves us to do everything in our power to place ourselves in a position, should death occur, that we may be able to conscientiously say that we have taken every precaution, were thoroughly prepared, and have given our undivided attention to our patient.

Time will not permit me in this paper to discuss or even refer to the many methods of administering an anæsthetic, but I shall give you only what I have found to be a successful method, and a few hints that may be of benefit to you.

If possible, know your patient long enough to determine for yourself how you must handle him or her. Therein lies the great secret of proper anæsthetization.

Bearing in mind that the phenomena of anæsthesia are largely dependent upon temperament, age, physique, quantity and quality of blood, state of the respiration, circulation, and other factors, we can not fail to recognize the advantages of ascertaining as far as possible the condition of the patient intrusted to our care. In the majority of cases a brief inspection is all that is necessary. The more practice the anæsthetist has had the less need will there be for a systematic examination; but even so, it is better to err on the side of an unnecessarily cautious investigation than to overlook symptoms or signs which, if recognized, would be of service in conducting the administration. It is certainly erroneous to argue that, as the patient must have an anæsthetic, there is no need to ascertain his fitness for it. By carefully taking into consideration the condition of the patient we not only place ourselves in a better position to decide which anæsthetic to choose, but we are enabled to anticipate the occurrence of important symptoms that might arise during the administration.

A great deal of valuable information, both positive and negative, is afforded by the general appearance and bearing of the patient. Let us in a few words consider

* Read before the Missouri Medical College Alumni Association, April 15, 1899.

what can be learned by simply observing the individual before us.

Should he walk to the operating table, his mode of progression may afford us information. We should notice whether he moves actively or whether with considerable hesitation or difficulty. Should the exertion be followed by breathlessness, we ought specially to bear the fact in mind. Should the patient be partially or wholly recumbent when we are called upon to anesthetize him, we should notice what position is assumed by choice. We should more particularly pay attention to the number of pillows the patient requires. Those who suffer from chronic bronchitis, emphysema, other affections of the air-passages, or extreme abdominal distention, almost invariably insist on being propped up to a greater or lesser degree. Marked orthopnea will attract attention, and should be regarded as a very unfavorable symptom. Patients suffering from unilateral pulmonary or pleural affections will probably be found lying on the diseased side. While observing and drawing our inferences from the walk or posture of the patient, we are able, as a rule, to roughly estimate his age. It must be remembered that the anesthetist is concerned as much with the apparent as the real age of his patient.

Temperament, too, which plays an important part in determining the manner in which an anæsthetic is taken, usually quickly shows itself on these occasions. This is more particularly the case with hysteria. It must be remembered, however, that women who are liable to outbursts of hysteria sometimes conceal their want of control so efficiently that the observer is deceived. The overworked and highly strung patient will be recognized, and should be treated with the utmost gentleness and care. Previous excesses in alcohol, as a rule, present little or no difficulty in their detection. The general physique of the patient will be observed. Gross, flabby individuals, with a large abdomen, muddy complexion, and double chin, will probably not be easy subjects to manage. Florid, muscular young men, who live an outdoor life and enjoy excellent health are also likely to give the administrator some difficulty. Persons afflicted with extreme obesity may also be regarded as bad subjects for certain anæsthetics, especially ether. Conversely, patients of slim build and more or less anæmic in appearance do particularly well during general anæsthesia.

The color of the patient's face and lips should be noticed. A florid, rosy tint denotes, as a rule, a good state of health and the absence of nervousness or respiratory derangements. The hectic flush, however, must not be allowed to deceive. Florid, and more especially dusky-looking and congested looking patients will be very likely to show cyanosis if air is withheld even to a slight degree. The pallor of true anæmia is readily recognized. Apart, however, from this pallor we must remember that very nervous and apprehensive subjects

are prone to be much paler than usual at the time of administration. Their pallor disappears when anæsthesia is established, and, often to the surprise of the anesthetist, to whom the patient may be a stranger, a good, florid color will persist throughout the administration.

The anesthetist should take special note of the manner in which respiration is performed, and if any marked abnormality in this direction is detected, a further examination of the patient should be made. If there is no obvious shortness of breath or distress in breathing, and if the respiratory movements are quiet and the color of the lips good, there is, as a rule, no need for any further examination. It is usually a good plan, however, to ask the patient to take a deep breath. In this way the administrator will see whether the chest expands freely and whether the respiration is principally thoracic or abdominal. A loose, frequent, or hollow cough should not escape attention.

The pulse should invariably be felt, and, as a general rule, it is a good plan to apply the ear or stethoscope to the chest. Feebleness, irregularity, intermittency, or marked slowness of pulse should lead to further inquiry. The oral cavity should be inspected. Artificial teeth, even though firmly fixed and apparently safe, should always be removed, so as to avoid the chance of their becoming lodged in the trachea and strangling the patient. If a partial or complete nasal obstruction is present, in order not to give trouble a mouth prop should be inserted so as to give an oral air way.

Before administering the anæsthetic certain appliances and drugs should be at hand, and by that I mean, so near that the anesthetist can put his hand on whatever he wants the instant he needs it: An instrument for opening the mouth and, if necessary, maintaining it in this position. A forceps, preferably one with a flat blade, so as to be able to grasp the tongue firmly, but at the same time not lacerate it. Besides this forceps, a thin, long forceps should be at hand with which to grasp small sponges for wiping out the mouth and pharynx. Of drugs, nitrite of amyl, best in the shape of five-minim pearls, which can be readily crushed and used by inhalation. Strychnine sulphate, one sixtieth or one fortieth of a grain, should be kept ready in a hypodermic syringe. Nitroglycerin, digitalis, aromatic spirits of ammonia, and whiskey. The Bliss-Moore Co., of St. Louis, have got up for me a portable case containing these articles.

Just a few words regarding the patient's clothing during anæsthesia: It must always be loose, no constrictions of any kind to be allowed to remain on the body. The patient should either be clad in a warm dressing gown or wrapped in a blanket, especially if feeble or in advanced years.

Before beginning the remarks of the mode of administering the anæsthetic, I want to call particular attention to the all important rule that the stomach and

bowels of the patient should be empty. I have made it a rule never to give an anæsthetic when I ascertain that the patient has taken food three hours or less before the time of operation, unless the case is of an emergency character, when the exception becomes necessary. This precaution avoids the possibility of the patient strangling from vomited material in the trachea while in no condition to dislodge it, and at the same time prevents the vomiting from disturbing the surgeon. Now, as to the choice of the anæsthetic and the mode of its administration.

Conditions being equal, my preference is for ether. Perhaps I lean toward ether because I have given it oftener than chloroform, and, therefore, feel more at home with it. I am not of the opinion that so often is expressed that one can give an overdose of ether and the result not be as serious as if it were chloroform. I believe a good rule to follow is to give the anæsthetic to the patient, and not the patient to the anæsthetic; in other words, give just as much anæsthetic as is necessary and not one drop more. It has been my great privilege to administer anæsthetics more than six hundred times for Professor H. Tuholske, and I know that the same careful and conscientious way which he carries out in every step and detail of his operations has been forced upon me in the giving of anæsthetics. In his service I have certainly learned that, all things being equal, the less of the anæsthetic drug that is given the better will the patients do; also that patients have a greater tolerance for pain under these circumstances than is often credited to them. Several times when the extreme weakness of our patient prohibited the continuance of the anæsthetic, have I seen him perform celiotomy, handle the abdominal viscera, yes, even make intestinal anastomoses with the patient wide awake. So, also, have I seen him perform craniectomy entirely without an anæsthetic; also resection of the superior maxilla.

I have tried the open and closed methods of etherization, and I believe the open way to be the better. I think the Allis inhaler, which allows a certain amount of admixture of pure air, brings about a safer anæsthesia, and certainly a pleasanter one for the patient. I have found pupillary reflexes an infallible guide to the degree of narcosis. No attention is ever paid to other reflexes. I regard touching the cornea as unscientific as it is unclean. It tells you nothing more than that your patient is unable to resent the insult. A contracted, immovable pupil teaches us that we have surgical narcosis; a dilated, immovable pupil predicts danger everywhere; while, again, a dilated pupil which reacts to light shows partial anæsthesia. I have found that pure air often revives patients without the use of drugs.

In conclusion, I wish to suggest a safe rule to guide the anæsthetizer in his work—viz., do not start the administration before everything is ready for the operation. Keep your patients just under enough to allow the surgeon to do thorough work, and aim to have them

return to consciousness as soon as they reach their bed-rooms.

1721 WASHINGTON AVENUE.

THE INOCULATION THEORY OF MALARIA.

By WALTER B. JAMES, M.D.

By the inoculation theory of malaria, at the present day, we mean the theory of the inoculation of the disease by mosquitoes; a theory which is closely associated with the names of Manson in England, Ross in India, and Bignami, Grassi, and others in Italy.

The possibility that mosquitoes stand in a close relation to the malarial poison is not a new idea. It is mentioned by some of the Roman writers at about the time of the Christian era. It has for many years been a matter of popular belief among the natives of tropical countries, as Italy, India, and Africa, and was also suggested many years ago in this country.

That malaria may be conveyed from diseased to healthy persons by direct intravenous injection of blood taken from persons suffering from the disease was conclusively proved in the early days of the study of the malarial organism.

In support of the theory that there is a fairly close relation between the poison of malarial disease and mosquitoes, many facts of common observation may be given. For instance, the malarial season is generally that at which mosquitoes most abound. Again, in a malarial region mosquitoes are almost always found, although the converse of this is by no means true.

The physical conditions which produce mosquitoes are also those which are supposed to predispose to the development of malaria, such as the presence of pools of stagnant water, or rank decaying vegetation with the presence of moisture and heat.

Precautions which are found to be of service in protecting from malarial disease are at the same time effective against the attacks of mosquitoes, such as the draining of neighboring pools or swamps, remaining indoors in the evening, sleeping at a considerable elevation above the ground, and, moreover, it has been claimed by some travelers in tropical climates that sleeping under nets has secured immunity from malarial attacks.

Laveran in 1891, Pfeiffer in 1892, Manson in 1894, and Bignami and Mendini in 1896 all suggested the possibility that the solution of the malarial problem was to be looked for along this line of inquiry. But to Manson especially belongs the credit of having first attacked the question seriously, and of having contributed facts of real value in its settlement. He interested Ross, a British surgeon in India, in the matter, and it is really chiefly to the studies of the latter that we owe most of the facts upon which the inoculation theory of malaria is based.

To McCallum, Bignami, and a number of others,

however, is due much credit for additional observations; while the very valuable work of Professor Smith on the ætiology of Texas cattle fever has done much to clear up the relations of malarial disease. I shall best use the short time at my disposal if I state briefly the main facts in the matter which have been observed, and then indicate the bearing which it is claimed they have upon the nature of malarial disease.

Manson observed that the flagellated bodies developed in microscopical preparations only in blood that had been for some time removed from the vessels, and he therefore concluded that this stage in the development of the organism took place under natural conditions outside the body.

Then, noticing that the body from which the flagella are protruded has no apparent apparatus for penetrating the vessel walls, he decided that the services of some outside agent were necessary, and naturally turned to the mosquito as the commonest parasite living upon human blood.

Ross, studying blood from the stomachs of mosquitoes that had fed upon malarial subjects, found that seventy per cent. of the crescentic bodies present had developed flagella.

Moreover, in the wall of the stomach in such mosquitoes, there are found hæmatozoa which appear to be malarial organisms that have penetrated into this structure and then become encapsulated.

Ross now took up the study of what is called bird malaria, which had already been investigated by Danilewsky and others.

Many birds, especially in tropical climates, suffer from the presence in their blood of parasites which in appearance and in manner of development closely resemble the malarial parasite of man. Two varieties of these are especially important, called *Halteridium* and *Proteosoma*.

Ross reasoned that facts demonstrated in the life history of these hæmatozoa would probably at least throw some light upon the problems of the human parasite. He found that if mosquitoes were fed upon the blood of birds infected with *Proteosoma*, after a certain time their stomach walls were found to contain pigmented cells resembling those which have just been referred to, and which are apparently a stage in the life history of the organism.

In the mean time, McCallum, studying blood containing *Halteridium*, found that certain of these hæmatozoa left the blood corpuscles in which they had developed and then threw out flagella. These flagella then separated from the parent organism and wandered about in the blood plasma until they met another *Halteridium*, into which they entered. The latter then took on motile powers and showed a marked ability to penetrate various tissues.

In the stomach wall of mosquitoes filled with *Proteosoma* blood, Ross found certain pigmented organisms

which appeared to be a coccidium or encysted stage of the parasite. If these were crushed they were found to be filled with minute rodlike bodies which he called germinal rods, and which he believed to be spores.

The inference was then drawn that the sequence of events in *Halteridium* and probably also in *Proteosoma* is as follows: The organism taken into the stomach of a mosquito from an infected bird, and inclosed in a blood capsule, leaves its blood cell and then throws out flagella. These flagella are then set free, and, being actively motile, wander about in the plasma until they meet another organism, into which they enter, and then act as fertilizing agents.

This latter organism then becomes motile and acquires the power of penetration and then enters the stomach wall.

Here it enters upon a coccidium or encysted stage and develops within itself a large number of germinal rods which correspond to spores, and which are then ready to initiate a new generation of the hæmatozoon.

In the mosquito there is a gland which is known as the veneno-salivary gland. It is situated in the insect's head, and its duct communicates with the proboscis. Its function is to furnish a poisonous secretion which is injected into the tissues of the victim after the insect has made its puncture. This secretion is supposed to produce a local paralysis of the tissues and so hinder the natural retraction of the walls of the smaller vessels which would prevent a free flow of blood into the wound.

In the cells of this gland in mosquitoes fed upon *Proteosoma* blood Ross found enormous numbers of germinal rods.

Next he took sparrows in whose blood the *Proteosoma* was found. Upon these he allowed mosquitoes to feed. He then allowed these same insects access to sparrows from whose blood *Proteosoma* had been shown to be absent. After a certain time the hæmatozoa appeared in the blood of these latter, and in this way he was able to prove his ability to transmit the disease from infected to healthy sparrows through the agency of mosquitoes.

Regarding *Proteosoma* in birds, then, it seems fair to assume that the mosquito may serve as an intermediary host, but whether it is its only intermediary host or not we do not know. Moreover, it is fairly proved that the disease may be communicated by the bite of infected mosquitoes.

Reasoning by analogy, Manson and Ross and most of the Italian observers believe that the same holds good for the malarial poison in man. In support of this is the fact that mosquitoes fed upon natural blood show similar pigmented and apparently encysted forms of the organism imbedded in the stomach wall.

A recent and very important observation of Bonami lends support to this view. He took a man who had been under observation in the hospital for several years,

and who was known to be free from malarial disease. He was kept in a small room in which a large number of mosquitoes, gathered in an intensely malarial district of the Campagna, were liberated. They bit the patient freely, and in a few days he was attacked with typical malarial fever and showed the organisms in his blood.

The ability to act as host to *Halleridium*, *Proteosoma*, or the malarial organism does not belong equally to all mosquitoes. It is found in each case that in order to obtain the above results it is necessary to have certain definite species of the insects.

The most recent observations which we have, and the news of which has reached us only within the past few days, are from Grassi, Bignami, and Bastianelli. They have made an elaborate study of mosquitoes fed upon patients suffering from æstivo-autumnal fever and tertian fever. They used a certain species of mosquito called *Anopheles claviger*, which is fairly abundant in the neighborhood of Rome, and which is found to answer best for the purposes of these experiments. Their results confirm in almost every particular the observations made by Ross in studying *Proteosoma*, and seem to justify his inference that the life histories of the two forms of hæmatozoa are practically the same.

The question now arises, Are the observations which I have briefly outlined trustworthy, and, if so, are the inferences that have been drawn from them justified? It is only fair to state that as yet but few experiments have been made and published confirming them. This is due partly to the fact that Ross's publications are themselves only a few months old, partly to the great practical difficulties which stand in the way of the carrying out of such investigations. In the studying of the parasites of such small insects as mosquitoes, the highest degree of technical skill is required, and more than ordinary patience. Moreover, the work can be done only in a malarial region, and generally far removed from laboratory facilities. To one who has had practical experience of the difficulties met with in dissecting out and studying the stomachs of mosquitoes, it is surprising that even so much should have been already accomplished.

It is of much interest, however, to know that Ross's preparations of mosquito dissections have been shown to Laveran, Koch, and Nuttall, and that they all independently regard them as convincing evidences of the trustworthiness of his statements, and they all, in their most recent publications or interviews, express a belief in the truth of his theory.

There remains, however, a great deal of work to be done before we may regard it as absolutely proved, and even then but a small part of the life history of the malarial protozoon will have been cleared up. But even as Ross's work stands at present it constitutes the most important contribution to the study of malaria that has been made since the publication of Laveran's

original work giving an account of the discovery of the organism.

Many questions suggest themselves for solution before practical use can be made of the facts already determined. For instance, if the mosquito is the intermediary host, is it the only one, and is it thus essential to the development of the poison in any given locality, or may the organism find shelter in other insects as well? Again, if malaria is acquired by the bites of mosquitoes, is this the only way in which it may be taken? In order to answer these various questions it will be necessary to follow out more closely that part of the life history of the organism which is passed outside the human body, and also perhaps outside its mosquito host. Facts are being gradually accumulated bearing upon these questions.

Bignami and his associates have demonstrated that two days after æstivo-autumnal blood rich in crescentic bodies has been taken into the stomach of a mosquito, the coccidium forms have found their way into the stomach and intestinal wall, and lie encapsulated between the muscle fibres. On the sixth day they have increased enormously in size and project into the lumen of the alimentary canal. Very gentle pressure at this stage suffices to rupture the cyst and set free in the intestine myriads of the germinal rods or spores. It is supposed that these spores then find their way into the water.

The question comes up, Can man now be infected with malaria by drinking this water, or is it more likely that the spores find their way into the larval forms of mosquitoes, remain with these until they develop into the full-grown insects, and so are again conveyed to the animals upon which the mosquitoes feed? It is generally thought that the latter is more probable; this would be closely analogous to what is known to take place in the case of the protozoon of Texas cattle fever, the cattle tick being the intermediary host.

Showing the widespread interest that has been aroused in this question, the Natural Science Department of the British Museum has recently published and distributed throughout the British Colonial Service a small pamphlet giving a description of the best methods of catching, preserving, and studying mosquitoes.

The British Government has also sent a commission abroad to investigate the methods used by Bignami and his associates in Italy and by Ross in India.

The German Government also has sent Koch to Africa to pursue there his studies in the inoculation theory of malaria.

The mosquito theory would help to explain another phenomenon which it is stated has been observed by physicians—namely, that certain localities which had never before been malarious have become so after the migration into them of persons coming from malarious countries. It is easily conceivable that healthy mosquitoes taking the blood of such malarial individuals may die and fall into pools of water, having first laid

their eggs in them and so infect these pools, and gradually change a nonmalarial into a malarial district.

Should the mosquito-inoculation theory of the disease be finally proved, it would render the outlook for prevention far more hopeful than it has ever been. In many localities mosquitoes may be much more easily got rid of than is generally believed to be the case. Careful attention to the drawing off of all stagnant water will sometimes remove the pest. Where such water can not be drained, kerosene may from time to time be floated on the surface, and is said to prevent the development of mosquito larvae. Thus the theory is one of the greatest practical interest to the entire community, and the present indications point to the rapid accumulation of a still further mass of facts of great scientific interest.

SURGICAL OPERATIONS DURING HYPNOTIC SLEEP.

By ARTHUR MACDONALD,

WASHINGTON, D. C.,
MEMBER OF THE SOCIÉTÉ DE L'HYPNOSLOGIE DE PARIS.

I DESIRE to give somewhat in detail two cases of surgical operations during hypnotic sleep by Dr. Schmeltz, of Nice.

The writer may be allowed to say that, while attending clinics, he has witnessed the extraction of a large, painful tooth (by Forel, of Zürich) during hypnosis, where the patient, who was an intelligent trained nurse, had not the least consciousness of the operation.

While there can be no doubt that in certain cases hypnotism may be as serviceable in surgery as the usual anesthetics, we, however, do not believe that it is generally practicable. But it is interesting to note special cases under special conditions in which it has been useful.

CASE I. Amputation of the Breast.—Miss M., twenty years of age, born in Italy, consulted Dr. Schmeltz for a swelling in the right breast. During the examination of her malady, which was a very large sarcoma, he observed that the young woman could very easily be plunged into a hypnotic state. By a steady gaze and a few downward passes, he in a few seconds put her to sleep, catalepsy and anesthesia being apparently complete. As treatment, the doctor proposed a complete ablation of the diseased glands. The neighboring glands were in no way hardened. Her general condition was good, and there was no inherited cancer in the family.

The young woman, with the consent of her parents, readily agreed to be operated upon under hypnotic anesthesia.

Desiring to be absolutely sure of the success of the operation, Dr. Schmeltz hypnotized his patient at intervals of two and three days, and was successful, especially as to the anesthesia—in fact, disinfecting her—was stuck deep into different parts of her body, without producing a shadow of pain.

On the day set for the operation, in spite of the suggestion made the day before for the young woman to be

at the doctor's office at 7.30 A. M., she did not arrive until 9, and then entered reluctantly. Her parents had indiscreetly told her of the time set for the operation, and it was impossible to obtain complete anesthesia. It was not until after the departure of the other physician, whom Dr. Schmeltz had invited to be present, that she regained confidence. The anesthesia was then produced and, owing to a suggestion which led her to believe that the operation would be postponed a week, all fear disappeared. She declared during the sleep that she had been terrified by the thought of the operation, and therefore could not sleep as desired. She gave assurance that the operation could take place next day, because on waking she was convinced that she had eight days before her.

The next day she arrived at the hour fixed during the sleep. Anesthesia was complete from the first, and the patient seemed admirably disposed.

Two other physicians assisted Dr. Schmeltz. After a minute examination of the hands and diseased part, Dr. Schmeltz made the classic oval incision for the amputation of the breast, which permitted him to take out that much-diseased organ with the aponeurosis of the large pectoral. A thorough examination of the axilla showed that the ganglia were not diseased. After five tubes were inserted the wound was closed by means of thirty-two metallic sutures. During the entire operation, which lasted about an hour, the part was continually washed with a sublimate solution. Ten arteries were involved and were twisted by the forceps. After a fresh wash of sublimate had been applied the region was covered with iodoform, making an antiseptic and compressive dressing.

At the beginning of the operation the assistants were somewhat excited, and begged the operator to have chloroform and ether in reserve; but they were quickly reassured when they saw the patient absolutely insensible in an anesthesia such as is obtained by large doses of chloroform.

Dr. Schmeltz operated slowly and at his ease. The patient appeared to feel very gay, and from time to time laughed loudly, as though to testify that she felt no pain. To aid the operation she took the most favorable attitudes, extending her right arm, and thus avoiding the necessity of having it held.

The results of the operation were satisfactory in every respect; her temperature did not rise above 37.3° C. (99.1° F.). The tubes were withdrawn the third day. Until a complete cure was effected, which was on the fifteenth day, but one dressing was made, consisting of iodoform and absorbent cotton. The sutures were removed as soon as the reunion was complete.

Throughout the operation the patient's face was very pallid, but the pupils of her eyes did not dilate, and her pulse was not feeble.

A number of physicians saw Miss M. at this time; they also saw the tumor, which weighed about four pounds.

CASE II. Ectropion of the Lower Left Eyelid.—Miss V., eighteen years of age, was attacked by ectropion when ten months old, as a result of an abscess in the sub-orbital region which had been lanced by a physician.

She had undergone two operations and the lid fell lower. When she consulted the doctor she told him that she had suffered so much from the inhalations of chloroform that she would never again undergo an anesthesia produced in that way.

A series of ten minutes sufficed to convince the doc-

tor that the operation could take place during a state of complete magnetic insensibility. Dr. Macario and Dr. Huillet were invited to be present at the operation.

All the usual antiseptic measures were taken, and, after putting the patient in a profound sleep, her eye was washed with a sublimate solution of 6 to 1,000. The patient, in a state of somnambulism, at once said, "That is a very strong remedy that you use." When asked if the irrigation burned, she said, "Not at all; I do not feel the slightest pain."

A V-shaped incision was made in the lid and the fragment removed. Three pins were then placed parallel through the ends of the wound and a metallic thread united them. A wash of sublimate with vaseline and iodoform was spread on the seam; a dry antiseptic dressing held the eye immovable. The pins and wire were removed on the fifth day; the wound was thoroughly united, and healed without the shadow of a complication and without a drop of pus.

The operation was performed slowly, and the eye, without any aid whatever, remained wide open, in spite of the contact with the instruments.

Owing to the pallor of the face and *quasi* absence of respiration, it was for a moment believed that the patient had fainted, but the large, soft pulse showed that this pseudo-syncope was but the effect of hypnosis. The patient did not feel the slightest pain, and when she awoke she would not believe that she had been operated upon.

RUBBER GLOVES IN ASEPTIC ABDOMINAL SURGERY, WITH A NEW METHOD OF STERILIZATION AND BACTERIOLOGICAL PROVINGS.

By C. H. RICHARDSON, M. D.,

ALBANY.

[A Study from the Surgical Laboratory of W. G. Macdonald.]

STERILITY as applied to the bare hands is almost a relative term. I believe few surgeons' hands are ever absolutely sterile, regardless of the method used to accomplish that purpose. The subject then reduces itself to one of the degree of infection in nearly all cases where rubber gloves are not used. It is only a question of immunity or whether the leucocytes are capable of mastering the situation in a certain percentage of patients. If they do, primary union ensues; if not, suppuration. Hence it is that we sometimes see dirty surgeons get healing by first intention. Of course, if almost any of the recognized methods for cleansing the hands are conscientiously followed, the cases where suppuration will follow will be very few, but for the benefit of the *few* is this paper written.

It stands to reason that a patient with an impoverished condition of the blood and little vital resistance will have a suppurative wound from little infection introduced, when three times the amount in a healthful patient can es no trouble. We do not always know beforehand which patients possess these qualities and to what extent, so the only safe way is to introduce none at all, and this can be done by the proper use of rubber gloves and a rigid technique.

Not infrequently we see a surgeon, three or four assistants, and two or three nurses "washed up" for an operation, all either handling instruments or assisting the operator. I saw such an occurrence in one of the large hospitals in New York city not long ago. This is an unnecessary risk—a great risk. It could just as well have been reduced sixty-two and a half per cent. by reducing to three persons all told, and the remaining thirty-seven and a half per cent. to nothing by the scientific use of rubber gloves, and the operation done with less confusion and greater dispatch. I am familiar with no operation that requires more than one surgeon, one good assistant, and one nurse—that is, to come in contact with the wound. I venture to say that had cultures been taken from beneath and from the sides of the nails and between the fingers, three anyway, if not more, of the eight would have shown germs—perhaps not virulent ones, but as apt to be as not.

Suture material has been made the "scapegoat" in unfortunate infections in many cases where it was not at fault. It will never cause trouble if properly prepared. Catgut prepared by the camol method is absolutely germless. Silk by sterilization under steam pressure is aseptic. Silkworm gut by the nitrate-of-silver process, followed by the action of the autoclave, is beyond dispute. Any of the various suture materials can be sterilized by one of the above-mentioned methods. The proper preparation of dressings and instruments is a part of operating-room technique and familiar to every surgeon.

The field of operation can be rendered so nearly aseptic by careful preparation that the worst that can happen from this source is stitch-hole abscesses, which are rare nowadays. What is left? The air (?) and the hands. Why take any risk when it can be so easily avoided? Cotton or Lisle thread gloves were a step in the right direction, but they are used but little at the present time, as they only partly accomplished the desired result, consequently were quickly succeeded by rubber gloves, now generally used, or ought to be, by all up-to-date surgeons in the country.

The hands should be washed as carefully in all cases as though gloves were not intended to be worn, for, should an accident happen, then the chance of infection is reduced.

The following I believe to be the best system to accomplish the purpose, advocates of permanganate of potassium and oxalic acid, chlorinated lime, mustard, carbolic acid, etc., to the contrary notwithstanding. The finger nails should be cleared of gross dirt before beginning. Use sterilized water and change it often. With a boiled, stiff hand brush and green soap scrub for a period of five minutes (it is longer by actual time than it seems when hurried) the lower third of arm, forearm, and hands, giving special attention to the sides and base of nails as well as underneath them and between the fingers. A sharp-pointed stick (orange wood is the tough-

est) assists in this locality. This removes the superficial scales of epithelium harboring the staphylococci. An ounce of oil of turpentine now applied and thoroughly rubbed in forms a creamy emulsion, removing most of the oily sebaceous material always present, and is a mild antiseptic. Another application of brush and soap for two minutes, and then carefully rinse the hands in plenty of fresh, sterilized water. Have some one pour one or two ounces of ninety-five per cent. alcohol over the arms and hands, rubbing them at the same time. This further frees the hands from any fatty material. Submerge in arm basin filled with warm 1-to-1,000 bichloride solution the scrubbed area for five minutes, then rinse in normal salt solution to remove the bichloride solution remaining. If rubber gloves are to be worn, dry the hands with a sterilized towel. Have some one remove the pins from the towel in which the gloves are carried; remove the gauze wrapper yourself (it is sterile) and put on the gloves, which by the following plan of sterilization will require no powder shaken inside and will slip on as readily as a kid glove. It is well to now submerge the gloved hand in a 1-to-1,000 sublimate solution for two or three minutes and rinse in normal salt solution. Touch nothing from this minute but your instruments. If these procedures are rigidly carried out, a patient will never become infected from the hands, now the greatest source of danger in most well-regulated hospitals, the technique in other respects being first class.

Gloves are now manufactured without seams and so thin that the tactile sensation is but slightly impaired. True, when wet, the tissue grasped has a tendency to slip, but this can be remedied somewhat by having the ends ground or roughened, as suggested by Dr. Macdonald. Their cost is nominal—about a dollar and a half a pair—and with the method of sterilization soon to be described they will last indefinitely.

I think the principal reason that they are not used by every one is the trouble and difficulty of getting them on satisfactorily after the preexisting methods of sterilization. A few will be enumerated with their main objections or defects.

I. Boiling similar to that of instruments just before operation. They are wet and will not go on readily unless vaseline is used. This imparts a sticky, slimy sensation and is nonsurgical.

II. Boiling previously and attempting to draw on under bichloride solution. This leaves more or less water in the ends of the fingers and "bags" in the palms of the hands and between the fingers.

III. Boiling and drying by slow heat, then with bits of gauze laid about the fingers and rolled up in rubber sheet until ready for use. This necessitates handling and exposure to contamination, besides requiring powdered starch or soapstone shaken inside them when used.

IV. Packing the fingers and palms with gauze bandages to hold them open, put in the autoclave and

subjected to steam under pressure. This is the best method so far, but about the third time they are prepared in this way the fingers will adhere and tear when attempting to separate them. The heat is too great.

All of the above-mentioned objections are overcome by first washing the gloves in soda solution, inside and out, and holding for a minute over a heater or gas flame, reversing once. Dust liberally the inside with dry-heat sterilized soapstone. Wrap each pair in a double layer of gauze. Two pairs of, say, No. 8's for surgeon and assistant, and one pair No. 6 for nurse, laid on a towel and placed in a formic-aldehyde sterilizer* for two hours. Wrap in towel already at hand, mark sizes with graphite, and they are ready at any or all times for hospital or out-of-town use. Four or five sets can be prepared at a time as well as one. They are sterile, dry, already powdered, and can be put on in ten seconds.

I once saw a prominent surgeon wash his hands with ordinary toilet soap, take from his bag a pair of rubber sterilized gloves nicely done up in a sterile rubber sheet previously prepared, pick them up by the band, and, after shaking from a glass pepper box some starch powder, proceed to put them on. The nurse, being a stranger to his ways, had prepared a bowl of sublimate solution. Noticing it, he turned to me and said: "Bichloride is poisonous; it has no place in surgery," meaning, of course, if we are aseptic, there is no occasion for antiseptics. The theory is correct, but suppose an accident should happen to the gloves, as it does sometimes when operating. It would amount to about the same as doing the operation without washing at all, and, besides, the dangers of contamination when putting them on without having the hands as nearly sterile as possible to begin with. Completeness as to detail obtains here as well as in any other part of a rigid technique.

I am indebted to Dr. A. J. Lartigan, assistant director of the Bender Hygienic Laboratory, for furnishing me with pure cultures of streptococci, staphylococci, *Bacillus coli communis*, Klebs-Löffler bacillus, *Bacillus pyocyaneus*, typhoid bacillus, and yeast fungi. After having passed through the sterilizer, and then been a sufficient time in the proper culture medium for each, they showed absolutely no growth or life.

27 EAGLE STREET.

Therapeutical Notes.

Dionin in the Treatment of Morphinomania.—According to the *Presse médicale* for May 20th, Professor von Mering found dionin as being of great service in

* The principle of a cheap and serviceable sterilizer is a square tin box, with door and wire gauze shelves. Formic aldehyde pastilles are converted into pure formic aldehyde gas by heating over an alcohol lamp in a cup-shaped arrangement fitted to the chimney. Schering's is the one used by us.

the treatment of morphinomania. The following formulae are given:

- R̄ Dionin 4½ grains;
Distilled water 300 “

M. Fifteen drops to be taken two or three times daily in a little sugar water.

Or—

- R̄ Dionin 4½ grains;
Extract of licorice, sufficient to make thirty pills.

M. From one to three pills to be taken at bedtime.

For hypodermic injection the following formula is recommended:

- R̄ Dionin 1½ grain;
Distilled water 160 minims.

M. From one to three injections of sixteen minims each may be administered in the twenty-four hours.

The Preventive Action of Chloroform Water against Post-anæsthetic Accidents.—M. Weber (*Journal des praticiens*, May 6th), as a consequence of observations on a patient who had been submitted to chloroform medication by internal administration, and who was subsequently submitted to operation, recommends that for some weeks a patient to be operated on should, if possible, be placed upon the following mixture:

- R̄ Chloroform water 3,000 grains;
Tincture of badi-
anum (*Illicium ani-*
satum) or essence } of each, 4 drops.
of mint,
Tincture of anise, }

M. Filter after twelve hours.

Subsequently to his first accidental observation, M. Weber has experimented upon many patients and finds that this treatment, when practicable, prevents the superintention of the unpleasant accidents attendant ordinarily on the administration of chloroform.

For Stomatitis.—Dr. Cassine (*Nord médical*, May 15th) recommends:

- R̄ Distilled water, } of each.... 150 grains;
Neutral glycerin, }
Chlorate of sodium 15 “
Hydrochloride of cocaine 1½ grain.

M.

For local application. Or—

- R̄ Lemon juice, } of each 225 grains;
Glycerin, }
Boric acid, } of each, 15 “
Chlorate of potassium, }

M.

For local application.

Erosions or ulcers should be touched with silver nitrate, equal parts of iodine and glycerin, 1-in-20 solution of sulphate of zinc, or 1-in-10 of sulphate of copper, chromic acid, or other astringent.

Internally the author recommends from sixty to a hundred and twenty grains of the chlorate of potassium or sodium in divided doses in the twenty-four hours. These substances being eliminated by the salivary glands, he says, act as a sort of continuous collutory.

Napelline as a Substitute for Morphine and to Overcome the Pain following the Withdrawal of Morphine.—M. Rodet (*Presse médicale*, April 5th; *Medicine*, June) claims to have experimented extensively with various drugs in seeking a substitute for morphine

that would overcome the atrocious pains which accompany the abrupt or gradual withdrawal of the drug. He asserts that in napelline we have a remarkable sedative for the nervous system which favors sleep. To obtain the best effects, the substitute is to be given hypodermically. It is readily soluble in distilled water. The dose employed is not definitely stated, but from the solutions employed it would seem as if about five grains had been given in a day. The author speaks of the feeble toxicity of the substitute, though in this he differs from other writers. Foster's *Handbook of Therapeutics*, says *Medicine*, states that napelline is almost identical in action with aconitine, but not so powerful, the dose being from one twentieth to one third of a grain.

A Draught for Premenstrual Pains.—The *Lyon médical* for May 21st quotes the following from the *Revue médicale*:

- R̄ Codeine ¾ grain;
Chloral 15 grains;
Bromide of ammonium 15 “
Camphorated water 450 “

M.

To be taken in one dose on going to bed.

The *Lyon médical* adds: “Before employing this remedy, which can not be an agreeable one, we advise practitioners to try antipyrine in a dose of from fifteen to thirty grains. We have seen greater relief follow this treatment even than that which follows the hypodermic injection of morphine.”

Sensitive Dentine.—The *Southern Clinic* for June quotes the following from the *Dental Brief*: “Dr. C. B. Rohland, of Illinois, says: ‘By adding just sufficient carbolic crystals to cocaine hydrochloride, and rubbing together with a spatula until the cocaine is dissolved, a thick syrup is obtained which is escharotic, antiseptic, obtundent. With this he often obtains most gratifying results in the treatment of sensitive dentine in cavities of decay. It should be used with the rubber dam, dryness to the verge of desiccation secured, applied warm, and treated *in situ* with the hot-air syringe, as hot as can be borne, and again dried before excavating. If the first application fails to give the desired result, a second will almost invariably prove effective.’”

A Prescription for Tapeworm in Children.—The *Clinica moderna* for May 10th attributes the following prescription to Sassy:

- R̄ Black oxide of copper 75 grains;
Prepared chalk, } each.. 15 “
Magnesium carbonate, }
Gum tragacanth 150 “
Glycerin 75 “
Sugar 600 “
Water a sufficiency.

M. Divide into fifty lozenges.

S. Two or three to be taken daily.

Syrup of Arsenate of Iron.—The *Riforma medica* for May 12th credits the following to Griggi:

- R̄ Arsenate of sodium 5 ½ grains;
Pure ferrous sulphate 4½ “
Citric acid 12 “
Distilled water 150 “
Syrup 14,850 “

M.

From two to six teaspoonfuls daily, before meals.

THE

NEW YORK MEDICAL JOURNAL.

A Weekly Review of Medicine.

Published by
D. APPLETON AND COMPANY.Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, JUNE 24, 1899.

CHOLERA INFANTUM AND THE NURSING BOTTLE.

THE perils that surround the bottle-fed baby are manifold. If a liquid reasonably resembling breast milk in composition and temperature is put into its bottle, it is still in danger of sucking in septic and possibly specific germs that have been lurking in the rubber appurtenances of the bottle. The abomination known as the Alexandra nursing bottle, that familiar device for saving the nurse-maid trouble, has commended itself to the unthinking for many years, and its use has even been upheld by some physicians who should have known better, although one would suppose that the dullest comprehension could not fail to perceive the impossibility of keeping it clean—clean in the ordinary sense of the word, not aseptic. Most physicians whose practice has been largely among children have, it is true, inveighed against it, but hardly any heed has been taken of their statements, perhaps because they were not clinched by indisputable demonstration. Such a demonstration seems now to have been made, and it is by no means the least of the services rendered by bacteriology. To Dr. Wendé, the health officer of Buffalo, so far as our present information goes, is due the credit of having proved the agency of the "hose" bottle in causing cholera infantum.

The flexible external tube of the Alexandra bottle, as everybody knows, is made of soft rubber, a material which speedily becomes foul when kept in contact with impure liquids or those that readily decompose. Dr. Wendé has shown that this tube, after having been in use for a little time, contains in the depths of the rubber, to say nothing of its inner surface, micro-organisms that even boiling does not destroy, as is proved by the ease with which cultures of them are grown. In consequence of Dr. Wendé's demonstration the Buffalo board of health some time ago passed an ordinance forbidding the sale of the "hose" nursing bottle, and during the year or more that this enactment has been in force the cholera infantum mortality of Buffalo has been fifty per cent. less than before.

But this is not all. The elimination of the "hose" does not, of course, do away with all the dangers of bottle-feeding. Not only has the baby to be guarded

against bad milk, but the micro-organisms lurking in soft rubber still pursue it. Dr. Wendé finds that even the rubber nipple used when the "hose" is dispensed with soon becomes a nest for bacteria; so that in time even that must go, although it will have to be used, we presume, until a less objectionable form of nipple is devised. Dr. Wendé finds that the nipples made of white rubber are more readily infected than the black ones; therefore, so long as rubber nipples still have to be employed, the black ones are to be preferred. What is wanted now is a nipple combining something of the elasticity of soft rubber with the germ-proof quality of glass. Celluloid has been suggested as a material that might be made to fulfill these requirements, and we see no reason why it should not if properly treated. Something must be invented to supersede the soft-rubber nipple.

SANITARY ICONOCLASM.

THIS is an iconoclastic age. Bit by bit, we see old faiths, old ideals, old traditions, old cherished beliefs crumble away. The emotions, which used to reign with unchallenged empire, it is now sought to control on sanitary principles. The loving cup becomes an abomination as a dispenser of disease. That heavenly first kiss, which poets have raved about and all young people have cherished as the ideal moment of their lives, is threatened with extinction as a conveyer of infection. "Wine that maketh glad the heart of man" is only a vile poison after all, to be shunned like the plague. Even the "cup that cheers but not inebriates" has within recent days killed a man, we are told, within the precincts of a New York hospital, and is ruining the digestion, and consequently the health, of its myriads, and producing a race of neurotics. The soothing influence of "sweet tobacco," that has refreshed the weary, calmed the excited, stayed the hunger of the explorer when food was not forthcoming, and stimulated the energies of the student "sicklied o'er with the pale cast of thought," is the offspring of a vile and filthy habit. Even the physical laws of Nature are all turned topsy-turvy. It is no longer true that we can not see in the dark. The X rays have made it approximately possible to see through a brick wall. Space and time are both reduced to trifling obstacles by the telegraph and the telephone. And so on *ad infinitum*.

We have always been accustomed to believe in the relative purity of a country over a city life. Dwelling houses in town have been deemed as breeding places of disease, and we have turned restful longings toward

the dear old country homes of earlier and more simple days. But even that ideal is now destined to be relegated to the limbo of exploded superstitions.

Dr. Harvey B. Bashore, in an able article in the *Sanitarian* for June 19th on Some Common Sources of Impurity in Country Houses, displays to us the unsuspected dangers that lurk within and without their hitherto sacred portals. While city houses are for the most part built on a comparatively dry and impervious foundation, in the country house "the usual method is to dig a hole the required size, wall this with stones and mortar, and on this erect the superstructure without any precautions being taken to favor 'dryness'; whence it follows that country houses have almost invariably damp cellars. The old privy befouling the soil is a worse sanitary sin than the kitchen sink, bath-room, and water-closet of its town congener. In country houses the soil outside the kitchen door becomes the usual sink, until it is sodden with filth and becomes a hotbed of putrefaction and a first-class bacteriological laboratory for disease germs. The old farmyard, with its cowsheds, chicken yards, and pigpens, is a standing menace to the whilom sturdiness of the rustic race. The midden or compost heap is a permanent danger, rendering the soil and atmosphere fouler than even those of cities. The village duck pond, with all its classic associations that have formed a subject for the picturesque treatment of the artist and the poet, is simply a stagnant pool, which can not really be beautiful, since beauty implies cleanliness and wholesomeness, two qualities conspicuously absent in this connection. The dear old well and the village pump, that gave such pure water in the days of our grandfathers as to afford no excuse for indulgence in alcoholic liquors, are now but disguised cesspools. Says the author:

"The allurements of the 'Old Homestead' seem very enticing on the stage or on canvas, but under the exacting eye of the sanitarian, with his increased angle of vision, 'things are not always what they seem.' The vine-clad porch, with its wistaria and fragrant honeysuckle, where 'mother used to sit,' resolves itself into a damp, musty, sunless nursery of 'the chronic rheumatism which made mother's life a burden.' The old well, with its 'pure, sweet water,' has become a vast test tube of colon bacillus at least, if none other; and the delightfully pure air, redolent with the perfume of flowers, has become an air surcharged with moisture reeking with the gases of decomposition, from a befouled soil and a cellar soil and air saturated with the moldy debris of decayed vegetables. Such is not rarely the true story of the 'Old Homestead.'"

The worst of it is that all this is really true. Long-

continued settlement in one spot in the country does befool the surroundings to an extent which offsets the old-time advantages of pure air and the absence of the exhalations that perforce accumulate in the cities, where man crowds together in masses suggestive of an enormous sardine box. Cooperation in the towns sets to work to minimize these evils of overcrowding by removal and disposal of sewage and other sanitary measures; while the erstwhile purity of the country home is becoming gradually more and more a fancy of the past.

Theoretically, the outdoor, uncrowded country life is far better than the sweltering existence of the city; but long-continued tenancy of one spot as surely though gradually diminishes the advantages, while the labor and cost of proper sanitation, which in the cities is reduced to a minimum burden on the individual, is to a large extent too much for the unaided country dweller.

The fact is, that the great virtues of the country are attained by two classes only: first, the nomad tribes that strike and repitch their camps as often as occasion requires, and, secondly, not the pioneers who break new ground—for that has dangers, malarial and otherwise, peculiar to itself—but their next succeeding generation; after which the "well-settled ground" begins to get progressively pernicious as a place of residence for each succeeding generation.

If these considerations have no other effect, they may serve to induce us to set off against the overcrowding of the cities the advantages for health rendered by the possibility of sanitary cooperation in the reduction of the evils occasioned by the waste products of humanity, personal or economic.

It is not, however, to be considered that nothing can be done to minimize these defects of the country house, and it is for State boards of health to aid in this matter.

MARRIAGE AMONG LEPERS.

IN our issue for May 27th, in an article entitled *The Alleged Contagiousness of Leprosy*, we cited Dr. Roger S. Chew's interpretation of Vertheil's plan of separating the sexes in leper settlements, to the effect that its purpose was to prevent the hereditary transmission of leprosy. We have since received a very interesting communication from Passed Assistant Surgeon E. P. Stone, of the navy, who acquaints us with some notes made by him last year on the occasion of a visit to the Molokai leper settlement in Hawaii. Dr. Stone learned from Dr. Oliver, the resident physician, and from Dr. Day, of the Hawaiian board of health,

that there were usually about a thousand lepers in the settlement and no segregation of the sexes was attempted. On the contrary, marriage was encouraged, as it was believed that lepers were generally barren. As a matter of fact, only about forty children have been born in the settlement during the last fifteen or sixteen years, and it is not believed there that leprosy is congenital, but rather that it is acquired after birth by accidental inoculation. Only ten per cent. of the children born in the settlement have become lepers. In Honolulu, Dr. Stone further informs us, there is a home for the non-leprous children of lepers, and when a child born in the leper settlement has attained the age of two or three years and is still free from the disease, it is taken to this home to be brought up, or is reared by its relatives in some other island. The board of health has thus been enabled to watch the growth and development of these children, and Dr. Stone is convinced that its opinions are solidly founded.

This is strong testimony and most gratifying in its purport, for we believe that marriage should never be discouraged, far less forbidden, save under very grave circumstances. Possibly Vertheuil had in view the prevention of illicit sexual relations rather than matrimony among lepers, for his observation to the effect that the sexual appetite is heightened in them is corroborated, Dr. Stone informs us, by what has been observed in the Molokai settlement. It is Dr. Stone's opinion that Kalaupapa, the site of the Molokai leper settlement, is ideally situated for quarantine purposes, and that the system of managing lepers carried out by the Hawaiian government is very nearly perfect. He adds the hope that, now that the islands have become part of our domain, there will be no disturbance of that system, and that eventually the lepers in the United States may be sent to Kalaupapa. For our part, we are convinced that the Hawaiian board of health is doing an excellent work in the matter of leprosy, and we fully indorse Dr. Stone's deprecation of interference with the board's system.

THE X RAYS IN THORACIC DIAGNOSIS.

THE increasing efficiency of the X rays in medical diagnosis is beautifully illustrated by an article on Some of the Medical Uses of the Röntgen Light, by Dr. Francis H. Williams, of Boston, published in the *American Journal of the Medical Sciences* for June. A series of six unusually clear skiagraphs is reproduced, representing the normal thorax in full inspiration, pleurisy with extensive effusion, pleurisy with slight effusion, pneumonia in the seventh day of the disease, pulmonary tuberculosis, and passive congestion or edema of the lungs. The aid rendered to clinical examination by these remarkably clear pictures is very great,

the outlines of the heart, the trachea, and cesophagus, the visible part of the aortic arch, the ribs, and the clavicle showing in marked contrast to the clear space of the normal lungs. The diseased portions of the lungs in the various pictures also show up well. These illustrations are among the best we have seen, and are convincing proof that it is only a question of time ere a large part of the field of medical pathology will lie as open to visual examination as is that of surgical pathology.

STREET-CAR EXCURSIONS FOR CHILDREN.

THE steamboat excursions which are provided for children in the Atlantic cities, and probably in those of the Pacific also, leave nothing to be desired except their multiplication. It is gratifying to observe that the inland cities are prodding by the trolley-car lines to give their children excursions little if at all less enjoyable than our aquatic outings and doubtless quite as beneficial from the point of view of health. Numbers of these excursions were to be seen in Columbus during the recent meeting of the American Medical Association.

PARALYSIS AGITANS FOLLOWING AN INJURY.

THE curious fact of the development of typical paralysis agitans as a sequel of fracture of the lower end of the radius is recorded by Dr. Köhler (*Monatsschrift für Unfallheilkunde*, 1899, No. 2; *Centralblatt für Chirurgie*, June 3d). The patient was a perfectly healthy man, sixty-one years old, of normal heredity, and living in easy circumstances. It is particularly stated that he was in no wise excited by the accident.

GENITO-CRURAL NEURALGIA.

PERSISTENT pain in the genito-crural nerve, often accompanied with tenderness on pressure over that portion of the spermatic cord that occupies the inguinal canal, may be the expression of any one of a number of lesions. Donath and Hutt (*Wiener klinische Wochenschrift*, 1899, No. 11; *Gazette hebdomadaire de médecine et de chirurgie*, May 21st) record the case of a young man in whom it followed gonorrhoea complicated with inflammation of the left epididymis. It was felt along the course of the left spermatic cord, and radiated toward the crest of the ilium. A portion of the genito-crural nerve rather more than two inches long was excised and found to be normal in structure. For two months there was complete absence of pain; then it recurred, but in reduced intensity, and was accompanied by augmented sexual desire and virile power. Finally the pain disappeared again almost completely.

THE ATHENIAN PLAGUE OF THE PÉLOPONNESIAN WAR.

THE plague described by Thucydides as afflicting the 200,000 men immured in Athens in the second year of the war, the year 430 B.C., has been made the subject of study by Dr W. Eberlein, who has published a pamphlet which is reviewed briefly by Dr Gumprecht, of Jena, in the *Centralblatt für innere Medizin* for June 3d. It seems that the disease was acute in its onset, with a sense of heat in the head and burning in the eyes, followed by lividity of the tongue and throat, foulness of the breath, snoring, hoarseness, and cough

or vomiting and hiccough. There were great restlessness and insomnia, and vesicles and ulcers formed on the skin. The victims usually succumbed in from seven to nine days. Those who recovered were apt to be affected with gangrene of the limbs. To the remark that the essential nature of the plague is uncertain is appended the following clever rendering of one of Hamlet's sayings: *Es giebt eben mehr Dinge im Himmel und auf Erden, als wir uns in unserer Schulweisheit träumen lassen*, but whether it is Elstein's, Gumprecht's, or some other writer's is not clear.

GASTRIC DISTURBANCES IN THE EARLY STAGE OF CONSUMPTION.

THE by-symptoms of pulmonary consumption are often more distressing to the patient and more taxing to the physician than the essential manifestations. Dr. W. Croner (*Deutsche medicinische Wochenschrift*, 1898; No. 48; *Centralblatt für innere Medizin*, May 20, 1899) divides the gastric symptoms into two groups, according as they appear before or after the pulmonary affection has frankly declared itself. He is unable to trace them to either gastritis or anæmia, and is content to term them functional disturbances. He thinks there is no reason to dread overfeeding in such cases.

THE ROULETTE OF PREGNANCY.

YET another method of making boys or girls at will! This time it comes from Greece. Dr. C. Nicolopoulos argues in the *Grèce médicale* for April that the right ovary produces males and the left females, and that the ovaries exercise their function alternately, the entire puerperal period being regarded as the equivalent of one menstrual period. Whence it follows that if a woman has given birth to a male child, the first and each following uneven menstruation will prove the time for impregnation if a female child is desired, while the second and subsequent even menstruations are the proper times to fecundate if a male child is desired. This process might be termed the roulette of pregnancy, but there will probably be an inordinate number of zeros to *pairs* and *impairs*.

A POINT IN TREPHINING FOR THE RELIEF OF PRESSURE.

It is sometimes desirable to prevent the formation of new bone after the operation of trephining. At a recent meeting of the Paris Academy of Medicine (*Journal des praticiens*, April 29th) M. Cornil gave it as the result of clinical observations by M. Chipault and experiments by M. Berezowski that the dura mater became the starting point of new bone after trephining, and advised removing a disc of it in cases in which the formation of new bone was objectionable.

DEEP RESPIRATIONS AS A PROPHYLACTIC IN HEPATIC COLIC.

M. MÖBIUS (*Nouveau Montpellier médical*, April 30th) has found that in a patient subject to attacks of hepatic colic he was able to avert the crises by "massage of the liver," as follows: "The patient is directed, on first warning of an attack, to take slowly as deep an inspiration as possible, lasting at least five seconds; the

breath is retained for from fifteen to thirty seconds more, and then a deep expiration, lasting from ten to fifteen seconds, is practised. This operation is repeated several times. During this process the liver is alternately depressed and elevated, this action constituting a sort of massage. M. Möbius considers that the absence of hepatic movements is the most common cause of cholelithiasis, which explains, in his opinion, its greater frequency among women, with their thoracic respiration and corset immobilization, than among men.

"NO TEMPERATURE."

Nor infrequently, in reading the manuscripts of esteemed and valued contributors, whose professional attainments are beyond question, we find the expression "no temperature" in the description of the condition of a patient. Now, temperature is a property of all matter, living or dead, organic or inorganic. As patients (when not fictitious) are quite material beings, they must have a temperature, and so must their remains after death. Possibly the shades of the good have "no temperature"; as for those of the bad, we shall have to consult a Presbyterian minister before expressing an opinion on the subject. However, what our contributors evidently mean is that their patients had no abnormally *high* temperature, and therefore in such cases we take the liberty of adding the qualifying adjective.

INCOMPATIBLES IN PRESCRIBING.

THE necessity of a knowledge of this subject to prescribers is very markedly emphasized by a fatal accident which is reported by the *Lancet* (February 11th and April 15th; *Medical and Surgical Review of Reviews*, May) to have happened at Johannesburg in the Transvaal—a qualified physician prescribing one ounce of "Liq. Ars." in combination with five drachms of "Liq. Strychn." Now, liquor arsenicalis is an alkaline solution, and the alkali would naturally precipitate the alkaloid. Consequently it is not a matter for wonder that at the end the patient got a fatal dose of strychnine in the half teaspoonful of the mixture and was seized with convulsions, which terminated fatally. The same prescription had been ordered many times previously without evil results; but the danger was there all the time, and should have been known and avoided. It is as necessary for the prescriber to carry a knowledge of dangerous incompatibles in his head as of the toxic doses of poisonous drugs, for the subject is not one of those things that can be relegated to the bookshelf to be looked up when required. It may prove to be too late when the necessity for looking it up is recognized.

ASTHMA SEXUALE.

DR. F. GRAHAM CROOKSHANK (*Edinburgh Medical Journal*, June) calls attention to Peyer's views that asthmas are not infrequently set up by morbid hyperæmias and catarrhs of the genito-urinary tract, which conditions are often caused in women by fibroids, subinvolution, etc., and in both sexes by masturbation and perverted sexual manifestations. Dr. Crookshank records cases bearing out this view, and concludes that a sexual origin should be suspected for asthma in the absence of bronchial, cardiac, gastro-intestinal, or nasal excitation: 1. In young neurasthenic men given to sex-

ual perversions or excess. 2. In middle-aged women the subjects of uterine catarrh from fibroids and other causes, particularly when single. 3. In young women and girls who have given way to sexual irregularities. Even in the insane, the so-called asthmatic insanity, the author's experience shows that there is often a sexual nusus. The physiological relation between the nasal passages and the genital organs has long been known, and also that between the nasal passages and the bronchi, and the points cited it is well to bear in mind in cases of asthma.

A POSSIBLE ADVANTAGE IN EARLY HYDRO-CEPHALUS.

DR. HANSEMAN, of Berlin (*Zeitschrift für Psychologie*, March 7th; *British Medical Journal*, May 13th), apparently agrees with Perls and Edinger that a certain amount of hydrocephalus in early life may prove of advantage to the intellectual development of the individual by enlarging the skull so that the brain may have room for unusual growth. His article is on the brain of von Helmholtz, who, like Cuvier, was somewhat hydrocephalic in his boyhood.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending June 17, 1899:

DISEASES.	Week ending June 10.		Week ending June 17.	
	Cases.	Deaths.	Cases.	Deaths.
Typhoid fever.....	12	3	18	6
Scarlet fever.....	183	19	136	13
Cerebro-spinal meningitis.....	0	12	0	14
Measles.....	422	30	375	16
Diphtheria.....	227	37	219	31
Croup.....	10	7	10	10
Tuberculosis.....	134	137	128	117
Small pox.....	6	3	3	2
Chicken pox.....	52	0	62	0

The New Camp Sanitarium at the Presidio.—According to the *Army and Navy Journal* for June 3d, orders have been issued directing Colonel Charles R. Greenleaf, assistant surgeon-general, to proceed to San Francisco, California, to assume direction of the sanitary arrangement of the new model camp to be established at the Presidio for troops returning from the Philippines. Colonel Greenleaf has pronounced ideas regarding the drainage of camps, and after his inspection of Camp Meade, Pennsylvania, has determined to follow to some extent the general plan of that camp. The kitchens and latrines will be far removed from each other, so that there will be no repetition of the conditions that existed at Camp Thomas, Chickamauga.

Death of Dr. Charpentier.—The death is announced from Paris, on May 29th, of Dr. Louis Alphonse Charpentier. Dr. Charpentier was a professor and fellow of the Faculty of Medicine of Paris and a member of the French Academy of Medicine.

"Neglect, Dropsy, and Christian Science" as Causes of Death.—According to the *Chicago Medical Recorder* for June, a "Christian Scientist" died a few days ago

in Mount Vernon, New York, after a three-months' illness, during which she persistently refused medical treatment. The coroner indorsed on the death certificate that she died "of neglect, dropsy, and Christian Science treatment."

Death of Dr. Sinclair Coghill.—The *Lancet* for June 10th announces the death, on June 5th, of Dr. J. G. Sinclair Coghill, an eminent member of the staff of the Royal National Hospital for Consumption. Dr. Coghill gave an address on the treatment of tuberculosis on May 26th at the International Congress in Berlin.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, plague, and leprosy were reported to the surgeon-general during the week ending June 17, 1899:

Small pox—United States.

Los Angeles, Cal.....	May 27-June 3.....	1 case.	1 death.
Washington, D. C.....	May 27-June 10.....	2 cases.	
Jacksonville, Fla.....	June 3-10.....	5 "	
Chicago, Ill.....	June 3-10.....	1 case.	
Evansville, Ind.....	June 3-10.....	3 cases.	
Emporia, Kan.....	May 24-31.....	6 "	
Morton County, Kan.....	May 1-31.....	12 "	3 deaths.
Louisville, Ky.....	June 3-10.....	5 "	
Baton Rouge, La.....	May 24-27.....	1 case.	
New Orleans, La.....	May 27-June 10.....	5 cases.	
Boston, Mass.....	June 3-10.....	2 "	1 death.
Chelsea, Mass.....	June 11.....	5 "	
Fall River, Mass.....	From outbreak to June 13.....	32 "	
Albany, Minn.....	June 3.....	1 "	
Inver Grove, Minn.....	June 3.....	1 case.	
Minneapolis, Minn.....	June 3.....	2 cases.	
St. Paul, Minn.....	June 3.....	1 case.	
St. Louis, Mo.....	June 5-12.....	5 cases.	
Omaha, Neb.....	May 27-June 3.....	1 case.	
New York, N. Y.....	June 3-10.....	2 "	3 deaths.
Massillon, Ohio.....	May 27-June 3.....	1 "	
Portland, Ore.....	June 17.....	1 "	
Pittsburgh, Pa.....	June 3-10.....	1 "	
Danville, Va.....	June 7-14.....	19 cases.	
Newport News, Va.....	June 8-14.....	None.	
Norfolk, Va.....	June 8-14.....	1 case.	
Portsmouth, Va.....	June 8-14.....	None.	
Seattle, Wash.....	May 26-June 2.....	1 case.	
Milwaukee, Wis.....	June 3-10.....	2 cases.	

Small pox—Foreign.

Serra Leone, Africa.....	May 1.....	10 cases.	
Antwerp, Belgium.....	May 29-27.....	2 "	4 deaths.
Bahia, Brazil.....	May 1-20.....	3 "	
Rio de Janeiro, Brazil.....	Apr 21-May 7.....	26 "	19 "
Hongkong, China.....	Apr 22-May 6.....	5 "	4 "
Cairo, Egypt.....	May 20.....	5 "	
London, England.....	May 1-27.....	2 "	
Bombay, India.....	Apr 29-May 30.....	12 "	
Calcutta, India.....	Apr 29-May 6.....	2 "	
Madras, India.....	May 6-17.....	1 death.	
Athens, Greece.....	May 20-27.....	21 "	6 deaths.
Nagasaki, Japan.....	May 9-16.....	1 case.	
Quahaba, Mexico.....	May 27-June 1.....	1 death.	
Mexico, Mexico.....	May 28-June 1.....	6 cases.	3 deaths.
Rotterdam, Netherlands.....	May 27-June 1.....	1 case.	
Moscow, Russia.....	May 6-10.....	4 cases.	10 "
Odesa, Russia.....	May 20-27.....	2 "	2 "
St. Petersburg, Russia.....	May 1-10.....	11 "	1 death.
Buenos Aires.....	May 1-10.....	2 "	
Montevideo, Uruguay.....	Apr 27-30.....	1 case.	

Small pox—United States.

New Orleans, La.....	May 1-June 1.....	1 case.	1 death.
----------------------	-------------------	---------	----------

Yellow fever—Foreign.

Bahia, Brazil.....	Apr 21-May 20.....	218 cases.	65 deaths.
Rio de Janeiro, Brazil.....	Apr 21-May 5.....	93 "	59 "
Peruana, Colombia.....	Apr 20-June 3.....	4 "	1 death.
Yucatan, Mexico.....	June 4.....	1 case.	
Vera Cruz, Mexico.....	May 15-June 8.....		132 deaths.

Cholera.

Bombay, India.....	May 2-16.....	6 deaths.
Calcutta, India.....	Apr. 29-May 6.....	23 "

Plague.

Hongkong, China.....	Apr. 29-May 6.....	98 cases, 86 deaths.
Bombay, India.....	May 2-16.....	614 "
Calcutta, India.....	Apr. 29-May 6.....	85 "
Tamsui, Formosa, Japan...	Mar. 29-Apr. 12.....	476 " 353 "

One case of leprosy at Matanzas, Cuba, June 6.

The Sanitary Work in Cuba.—The Marine-Hospital Service reports from Havana, Matanzas, Santiago, including Daiquiri and Guantanamo (*Public Health Reports*, Washington, June 9th), are highly satisfactory, and clearly show the vast benefits accruing from the American occupation. There were no deaths from yellow fever, and in Havana the deaths from all causes were much less in the week ending May 25th than in the previous week.

Changes of Address.—Dr. A. Stella, to 371 Lexington Avenue, New York; Dr. Parker Syms, to No. 50 West Forty-seventh Street, New York; Dr. J. C. Wharton, from Jamaica, Long Island, to No. 162 West Ninety-third Street, New York.

Naval Intelligence.—*Official List of Changes in the Medical Corps of the United States Navy for the Week ending June 17, 1899:*

GUEST, M. S., Passed Assistant Surgeon. Detached from the *Detroit*, June 20th, and ordered home to await orders.

BRAISTED, W. C., Passed Assistant Surgeon. Ordered to the *Detroit*, June 20th.

MAGRUDER, A. F., Surgeon. Granted leave for four months, with permission to leave the United States.

GATEWOOD, J. D., Surgeon. Detached from the bureau of medicine and surgery and ordered to the *Lancaster*, June 22d.

LOVERING, P. A., Surgeon. Detached from the *Lancaster*, June 22d, and ordered home and to await orders.

Marine-Hospital Service.—*Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending June 15, 1899:*

MURRAY, R. D., Surgeon. So much of bureau letter of May 15, 1899, directing Surgeon Murray to transfer property in his charge to Passed Assistant Surgeon W. J. S. STEWART revoked, and directed to defer departure to Key West, Florida, until the arrival of Surgeon W. P. MCINTOSH.

CARTER, H. R., Surgeon. To report at Washington, D. C., for special temporary duty.

BANKS, C. E., Surgeon. To proceed to New York for special temporary duty.

PECKHAM, C. T., Surgeon. To proceed to Sabine Pass, Texas, for special temporary duty.

BROOKS, S. D., Surgeon. Granted leave of absence for fourteen days. Upon expiration of the leave of absence granted by bureau telegram of June 12, 1899, to proceed to Portland, Maine, and assume command of the service.

MCINTOSH, W. P., Surgeon. Upon being relieved from duty at Louisville, Kentucky, to proceed to Mobile, Alabama, and assume command of the service.

WHITENBAKER, C. P., Passed Assistant Surgeon. Granted leave of absence for six days.

STEWART, W. J. S., Passed Assistant Surgeon. Bureau letter of May 15, 1899, directing Passed Assistant Surgeon STEWART to assume command of the service at Mobile, Alabama, revoked.

GREENE, J. B., Assistant Surgeon. Relieved from duty at San Francisco, California, and directed to proceed to Boston, Massachusetts, and report to medical officer in command for duty and assignment to quarters.

McMULLEN, JOHN, Assistant Surgeon. Upon being relieved of temporary command of the service at Portland, Maine, to proceed to Louisville, Kentucky, and assume command of the service.

ROBINSON, D. E., Assistant Surgeon. Granted leave of absence for three days (paragraph 181, Regulations, Marine-Hospital Service).

ULRICH, C. E., Acting Assistant Surgeon. Granted leave of absence for twenty-six days from June 5, 1899.

PECK, F. H., Hospital Steward. Bureau letter of March 15, 1899, directing Hospital Steward Peck to proceed to the Tortugas Quarantine Station for duty revoked.

RYDER, L. W., Hospital Steward. Granted leave of absence for fourteen days from June 15, 1899.

CARLTON, C. G., Hospital Steward. Relieved from duty at Egmont Key (Florida) Detention Camp and directed to proceed to New Orleans, Louisiana, and report to the medical officer in command for duty and assignment to quarters.

BECK, J. E., Hospital Steward. Relieved from duty at New Orleans, Louisiana, and directed to proceed to Mobile, Alabama, and report to the medical officer in command at that port for duty and assignment to quarters.

Appointments.

LINLEY, W. J., of Georgia, appointed Acting Assistant Surgeon, United States Marine-Hospital Service, for duty at the Savannah (Georgia) Quarantine Station.

LIPPITT, W. H., of North Carolina, appointed Acting Assistant Surgeon, United States Marine-Hospital Service, for duty at Wilmington, North Carolina.

Boards Convened.

Board convened to meet at the United States Marine Hospital, Stapleton, Staten Island, New York, at ten o'clock A. M., Tuesday, June 13, 1899, for the physical examination of an applicant for appointment as third lieutenant in the Revenue-Cutter Service. Detail for the board: STONER, G. W., Surgeon, chairman; HOBBS, W. C., Assistant Surgeon, recorder.

Board convened to meet at New York, at ten o'clock A. M., on Tuesday, June 27, 1899, for the purpose of examining candidates for appointment as assistant surgeon in the service. Detail for the board: STONER, G. W., chairman; BANKS, C. E., Surgeon; WILLIAMS, L. L., Surgeon, recorder.

Society Meetings for the Coming Week:

MONDAY, June 26th: Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, June 27th: Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Rome, New York, Medical Society; Richmond, Virginia, Academy of Medicine and Surgery.

WEDNESDAY, June 28th: New York Pathological Society; American Microscopical Society of the City of New York; Auburn, New York, City Medical Association; Berkshire, Massachusetts. District Medical Society (Pittsfield); Philadelphia County Medical Society.

Births, Marriages, and Deaths.

Born.

ATKINSON.—In Baltimore, on Monday, May 29th, to Dr. and Mrs. Albert S. Atkinson, a son.

Married.

CHASSAIGNAC — MORRIS. — In New Orleans, on Wednesday, June 7th, Dr. Charles L. Chassignac and Miss Jennie Morris.

ELLIOTT — BUIST. — In Spartanburg, South Carolina, on Monday, June 5th, Mr. Samuel Tilden Elliott and Miss Constance Somers Buist, daughter of Dr. John Somers Buist, of Charleston, South Carolina.

GOULD — MEADE. — In Medina, New York, on Wednesday, June 14th, Dr. Richard J. Gould, of Buffalo, and Miss Althea Meade.

GUILD — STONE. — In Waltham, Massachusetts, on Monday, May 29th, Dr. Edward Frank Guild, of Chelsea, Massachusetts, and Miss Nannie E. Stone.

HULL — OSTRANDER. — In Lansingburgh, New York, on Thursday, June 1st, Dr. Harry F. Hull, of Proctorsville, Vermont, and Miss Mildred M. Ostrander.

KAINES — WOLCOTT. — In Lykens, Pennsylvania, on Thursday, June 15th, Dr. Arthur Wiley Kaines and Miss Vida Blanche Wolcott.

MILLS — FELL. — In Buffalo, on Thursday, June 15th, Mr. Irving Judson Mills and Miss Grace Argo Fell, daughter of Dr. George Edward Fell.

SAVAGE — ALEXANDER. — In St. Augustine, Florida, on Thursday, June 1st, Mr. Henry Savage and Miss Helen L. Alexander, daughter of Dr. L. Alexander.

SLONINSKY — SHENKIN. — In Philadelphia, on Thursday, June 15th, Dr. George Sloninsky and Miss Pauline Shenkin.

Died.

BAYLIES. — In Taunton, Massachusetts, on Thursday, June 1st, Adeline Baylies, daughter of Dr. Alfred Baylies.

MILLS. — In Medford, Massachusetts, on Monday, June 5th, Hermon Franklin Mills, only son of Dr. George W. Mills.

Letters to the Editor.

BEN KING'S VERSE.

UNIVERSITY HEIGHTS, June 17, 1899.

To the Editor of the *New York Medical Journal*:

SIR: On page 824 of your last issue you refer to the unacknowledged clipping habit. I am therefore confident that you will welcome more complete information as to the authorship of the lines which you print on your last page To a Delinquent Patient.

The verses have reached you in a roundabout way, and evidently proper credit was not given in the journals from which you clipped.

Last year there appeared a modest volume entitled *Ben King's Verse*.* The verses To a Delinquent Patient appear on the first page under the title If I Should Die. These lines are a fair sample of the humor and human nature that characterize all of Ben King's verse, and invite one to peruse the volume further.

I offer this correction for the very reason that Ben King, a "Thomas Hood from Michigan," to quote Opie Read's biographical sketch, lived and sung almost unknown, and died a sudden and untimely death in 1894, without recognition. Since his death his verse has been collected and published in the little volume referred to. He wrote the poet's lament that "there was nothing to eat but food," Jane Jones, S'posin', and many other equally clever things, many of which have become almost so popular as to rank as slang, while yet Ben King was unknown.

Let us at least give just due to the dead.

WILLIAM J. GREANELLE, M. D.

MEASLES IN SCHOOL CHILDREN.

27 WEST ONE HUNDRED AND FIFTEENTH STREET,
NEW YORK, June 14, 1899.

To the Editor of the *New York Medical Journal*:

SIR: Probably the most important point in connection with "Koplik's spots" is the possibility of making an early diagnosis in hospitals, asylums, and schools. In such places the cases can be immediately isolated, and the spread of the disease prevented.

As medical school inspector, I have recently had an opportunity to demonstrate the value of this sign. In each of two classes a pupil took measles on the 8th of May. From that time I examined regularly in both these classes all those pupils who had come in immediate contact ("chums") and all those who had not already had an attack of measles. On the 16th two pupils, on the 17th two pupils, and on the 18th one pupil showed the characteristic spots on the buccal mucous membrane. These pupils, together with their brothers and sisters, were immediately excluded.

The patients presented a beginning eruption on the body in from twenty-four to forty-eight hours after the diagnosis was made.

On the 30th one more case occurred in another class. This class was then examined in the same way. Up to the present time there have been no more cases.

I think there can be no doubt that had the cases not been isolated so early, the spread of the disease would have been much greater.

I have lately seen a set of cases in which this sign was of assistance in excluding measles. During the warm weather a number of children presented a heat eruption, which to the unpractised eye might be mistaken for that of measles, especially in those cases in which it is limited to the face, the neck, and the skin behind the ears. In some cases conjunctivitis and bronchitis are also present.

I saw a case of this kind a short time ago in which a very experienced physician diagnosed measles. From the absence of Koplik's spots, I concluded that it was not. A few days later I saw the child. It did not have measles.

* Check, 1898, p. 100.

While on the subject of measles, I should like to say that I believe the spread of this disease could in many cases be prevented. A number of cases have come to my knowledge in which the health department has not been notified, either through neglect of the physician, or because the family had none.

Often in such cases the remaining children of the family are allowed to play with other children in the streets, or they are allowed to go to school.

A few days ago I saw a case in point. One child in the family had a rather severe attack of measles. As I came in, I found the little sister of the patient in the vestibule below, surrounded by a dozen of her friends from the block. Another child of the same family was attending school. The mother begged me not to report the case, as the child was in the grammar school and would not be promoted if she remained away from school. C. HERRMAN, M. D.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

XXIV.

CIVIL MALPRACTICE, INCLUDING GENERAL LIABILITY OF PHYSICIAN TO PATIENT.

Purpose of the Chapter.—The purpose of this chapter is to make a careful examination of the law governing the civil liability of physicians and surgeons, illustrating its application by particular instances and cases as fully as the limit of the work will permit. The examination will extend through the subject of civil malpractice, and will also include those instances of civil liability arising from acts either of omission or of commission which do not amount to malpractice.

No Liability for Refusal to take a Case.—In some localities there is a popular belief that a physician, by reason of the rights and privileges which he enjoys as such, is bound to undertake the treatment of any patient who requests from him professional services. There is in the law no foundation whatever for this belief. A well-known law writer, in referring to the subject, says: "No question can exist as to the legal right of a physician, unless he be an officer of the government charged with specific duties, which he thereby violates, to decline to take charge of a particular case."* But having once assumed charge of a case, we have observed in a preceding chapter,† he immediately sets in operation numerous implied contracts and presumptions of law regarding his qualifications to properly treat that case, and should he fail to fulfill these implied contracts, or comply with the presumptions of law, a civil liability immediately arises in favor of the patient to the amount of damages thereby sustained.

General Professional Requirements.—Perhaps the most fundamental of the professional requirements that we have heretofore observed are that one who undertakes to render medical services, holding himself out as a physician or surgeon, will be held by the law, first, to possess a reasonable degree of knowledge, skill, and

experience; second, to exercise ordinary care and diligence; and third, to use his best judgment in all cases of doubt as to the best course of treatment.*

Application of Rule.—Whether or not the amount of knowledge displayed or the degree of skill, care, and judgment exercised is sufficient in any case to fulfill the requirements of the law is a question of fact for the jury to determine from the evidence produced at the trial. To illustrate the application of the rule we will, as in previous chapters, examine the records of a few prominent trials. In the case of *Boldt vs. Murray*† the patient was suffering with a fracture of the inner condyle of the humerus. The evidence does not tend to show that the bone was not properly set. The evidence of the plaintiff was to the effect that the bandage was not put on the arm in the approved manner, but was rolled from the upper to the lower part of the arm, and so tightly as to prevent circulation, and that, although the hand and arm became swollen and the latter discolored, the bandage was left on; and that, by reason of the improper bandaging and the permitting of the bandage and splints to remain on in such condition, the circulation of blood was cut off, and, as a consequence, the flesh of the arm, being deprived of sustenance, sloughed off. The physician, on the other hand, gave evidence to the effect that the arm was properly bandaged, and that the unfortunate result of the injury was caused by the failure of the patient and his parents to obey the physician's directions, etc. Here was a case of direct conflict of evidence from which it was the province of the jury to determine the real facts. The court instructed the jury upon the law applicable to the case, as set forth in the above rule, whereupon they retired and found a verdict for the plaintiff, evidently believing the evidence given by the plaintiff and disregarding that given by the defendant. The judgment based upon this verdict the general term of the supreme court refused to reverse, stating in effect that the evidence of the plaintiff, if true, was sufficient to show that the defendant did not come within the legal requirements as to knowledge, care, and judgment, and that as to the truth of such evidence the jury was the only judge.

In the case of *Link vs. Sheldon*‡ *et al.*, the plaintiff, a lad of thirteen years of age, had fallen, striking with such force upon his hand and forearm as to produce a Colles's fracture and a dislocation of the ulna. The defendants were called and dressed the arm, placing a certain metallic splint, which should have been adjusted to the palmar surface of the hand, upon its back. The plaintiff's evidence was to the effect that the bandaging of the hand and arm had been so tight as to cause an inflammation and resultant suppurative, which in healing drew in the thumb and permanently deformed the hand.

The accident took place on Friday. It appears that the patient's parents became dissatisfied with the defendants' treatment of the case, and, hearing of the success of another doctor, employed him and dismissed the defendants on the following Tuesday morning, and that the defendants had nothing further to do with the case.

The evidence adduced by the defendants was to the effect that the injury was not an ordinary Colles's frac-

ture, but that the position of the bones was so reversed that the splint had to be used as applied by them; that the physical condition of the patient, in addition, was bad from feverishness; that the bandages were rightly adjusted; that the great inflammation discovered when the doctor who succeeded to the case was called in was due to their having been prevented by the parents from redressing the arm on Monday evening, as they desired to do; and, finally, that had the succeeding physician properly treated the hand in its inflamed and swollen condition by lancing instead of poulticing, no distorted condition of the hand would have resulted.

The jury returned a verdict for the plaintiff to the amount of four thousand dollars. The court of appeals, in refusing to reverse the judgment, said: "The evidence upon the material points was conflicting. There was more or less disagreement among the doctors; but it is impossible to say that there was not evidence tending to establish a lack of skill, or some neglect, on the part of the defendants. It was not necessary, in order to sustain the action, that there should have been proof of gross culpability upon the part of the defendants. It was sufficient to warrant a verdict against them that there was evidence of any failure on their part to exercise proper care, or of any neglect in the discharge of the duty they had assumed toward the plaintiff."

While the legal effect upon the liability of the defendants, from dismissing them at an early stage in the treatment of the case and employing another physician, is not pertinent to the question now in consideration, it is perhaps of sufficient interest to justify digressing. The liability of the defendants in such a case extends not only to injuries directly resulting from the ignorant, unskillful, or negligent treatment to which they have subjected the patient previous to the time of their discharge, but they are liable as well for all injuries directly resulting from such improper treatment, even though they are not manifest until after the case has passed to the care of another physician. If, however, such injuries are the result of any other cause than that of the improper treatment of the defendants, they are not liable therefor. Upon this point the trial judge charged that "if the jury find, from the evidence, that it is just as probable that the injury complained of was caused either by the original severe injury, or by the interference of the plaintiff's parents (in refusing to allow the defendants to redress the arm), or by the subsequent manipulations and treatment of Dr. — (who succeeded defendants in the treatment of the case) and others, as from the pretended tight bandaging, it is the duty of the jury to find a verdict for the defendants." This instruction was held by the court of appeals to properly state the law.

After laying down the general rule requiring a reasonable degree of competency, care, and judgment, the court, in commenting upon the evidence in the case of *Ritchey vs. West*,* said: "The concurring evidence of all of the physicians shows that the splints and bandages were not properly applied. Had they extended below the wrist, the evidence seems to show that they would have confined the wrist to its proper place. It is probable that such a practice would have tended, notwithstanding the fracture, to have held the broken bone more nearly to its place until a union was formed, and thus have prevented to some extent, if not altogether, the deformity and disability to use the hand. The physicians

also agree that the splints employed were not of sufficient width, as well as too short, for the treatment of the fracture, even if they had been midway between the wrist and elbow, as he supposed. And from this evidence it would seem that there must have been a want of ordinary skill, or great negligence, in the treatment of the case, in not detecting the dislocation of the wrist joint. The physicians all agree that this portion of the injury could have been easily detected by ordinary care and skill, and the fact that it had been and was still dislocated was afterward detected by a person who did not profess surgery or skill in such matters, and had previously had only slight experience in cases of fractured limbs. Then, if the evidence of the medical men who were examined as witnesses is to be credited, and it is supported by the fact that the dislocation of the joint was detected by a person professing to have no skill, there was a want of ordinary care or skill, or both, manifested in the treatment of the case."

Failure to Discover Extent of Injury.—It must not, however, be inferred from the preceding case that the failure of the surgeon to discover a serious injury is a fact from which incompetency or negligence will necessarily be inferred. This is well illustrated by the case of *Godney vs. Kingsley*.* In this case the patient was thrown from her carriage and sustained a fracture of her right arm. The defendant, a physician, was called and made an examination, but did not discover the nature of the injury, and supposed it to be no more than a bad bruise. Upon the second visit he informed the patient that her arm needed further attention, but she thought she was getting on toward recovery, and said that she would send for him if she needed him further. The arm became very greatly swollen, and it was finally discovered that one of the bones was fractured. By reason of the delay in discovering the fracture the injury became in a measure irreparable. As usual, the parties differed in their remembrance of the facts. A physician who had examined the arm before the defendant, supported the defendant in his statement that the extent of the swelling prevented an examination which was needed to discover the fracture. The medical experts also differed upon the question whether a skillful surgeon ought to have discovered the fracture, but all agreed that the swelling should have been reduced; but, as to this, the court very properly expressed the opinion that if the patient prevented that by directing the physician to make no more calls until he was notified, he could not be blamed for omission to diligently look after the case. The jury found that the arm was so swollen that a complete assurance of the extent of the injury could not be made from a careful and skillful examination, and that the swelling was suffered to continue because the physician was told to wait until he was sent for to attend further. They consequently exonerated the defendant.

(To be continued.)

Pith of Current Literature.

The Cause of the Reappearance of Pediculi Corporis. Dr. Allan Jamieson (*British Journal of Dermatology*, May) refers to the fact that in spite of all pre-

* *Ritchey vs. West*, 23 Ill. 385.

* *Godney vs. Kingsley*, 41 N. Y. S. R. 794, 16 N. Y. Supp. 792.

cautions as regards the boiling of clothing and the local applications of disinfectants to the skin, it is no uncommon thing for a recurrence of pediculi to take place after an apparent cure has been effected. The complaint, annoying though it is, is not one to admit of the constant supervision of the physician, and consequently proper investigations have hitherto been very difficult. Dr. Jamieson says that an old woman infested with these parasites was admitted recently to his ward in the Royal Infirmary, solely that she might be rid of pediculi, her friends promising that were she taken in and returned to them freed from the pest they would do their best to keep her clean in future. Every stitch of her clothes was at once removed and fresh linen put on. She had several carbolic baths. A careful examination of her skin was then made, and he found that attached to the minute lanugo hairs still remaining here and there on her back, and especially on her shoulders, were the ova of the pediculus. This, he says, accounts for the intractable nature of the complaint and its constant tendency to recur. The clothes in such cases may have been entirely replaced by fresh ones, and the patient washed, yet some of the ova clinging to the hairs, possibly in out-of-the-way localities, have retained their vitality, and no sooner are precautions relaxed, and the previous careless habits returned to, than these hatch and the pediculi reappear. It would seem, then, says Dr. Jamieson, that—the opinions of Besnier and Doyon, so strongly expressed, notwithstanding—those physicians are right in principle who recommend that patients affected with *Pediculi vestimentorum* should have baths of corrosive sublimate, or be treated with mercurial fumigations, though the reason why has not hitherto been supplied. A better plan is to rub paraffin over the whole body, and then give a warm carbolic-acid bath. The rationale of the suggestion already made by the author, that such patients should wear for a time porous bags containing fragments of sulphur next the skin night and day, is now explained. It is clear that even if one or two ova attached to the lanugo hairs escape destruction, the insects will in time assuredly reappear. The term *Pediculus corporis* he considers, on the whole, preferable to *Pediculus vestimentorum*.

Medicine in Mesopotamia.—From the *Lancet* for June 3d we learn that Dr. Christopher Johnston, an American student of the cuneiform inscriptions, has unearthed and translated some evidences of the medical conditions in Babylonia. There are several communications from physicians in Assurbanipal's library relating to sufferers from what appears to have been facial erysipelas, epistaxis, and other complaints. Arad-nana and Iqisa-Aphi would appear to have been physicians of note.

Cannabis Indica in Excessive Menstruation.—The *Port Wayne Medical Journal-Magazine* for May quotes from the *Therapist* the following: While the curette is the ideal instrument for attacking excessive menstrual flow, there remain a number of cases that will not permit operation, and others in which the trouble is entirely one of functional derangement. In such cases, especially where the exciting cause is an irritation arising in the Fallopian tubes or in the ovaries, ten- to fifteen drop doses of tincture of cannabis indica, given every three or four hours, are often curative. The administration should be commenced a few hours after the flow sets in, say from twelve to eighteen hours

after, and be continued until its effect is produced or the symptoms abate. Much will depend upon the character and purity of the product used as to the amount of benefit received. Upon this the *Journal-Magazine* remarks: A word of caution as to the use of cannabis indica may not be amiss, for it must not be forgotten that this drug is one of the most treacherous in the entire pharmacopœia. This is perhaps true largely owing to the difference in character and strength of the various preparations that are found upon the market. No preparation except one of recognized strength, as determined by physiological tests, should be employed.

The Dangers of Erythrol Tetranitrate.—An accident, by which a chemist lost his life, is reported by Colonel A. Ford, her Majesty's chief inspector of explosives (*Medical Press and Circular*, March 29th; *Medical and Surgical Review of Reviews*, May), to have happened at a tabloid factory at Dartford, on December 15, 1897. He was engaged in mixing tetranitrate of erythrol with finely powdered lactose in a mortar when an explosion occurred.

Tetranitrate of erythrol is explosive, and is more highly sensitive to percussion than dynamite or gun cotton. As it has lately come into some use in the place of nitroglycerin as a remedy for angina pectoris, the writer draws special attention to the dangers of handling this drug.

Endocarditis of Tonsillar Origin.—At a recent meeting of the Association of American Physicians, Dr. F. A. Packard (*Boston Medical and Surgical Journal*, May 25th) reported five cases of endocarditis all of which had been preceded by an attack of amygdalitis. The minutiae of the physical signs were detailed to insure the correctness of the diagnosis of endocarditis. In two of the cases it was certain that prior to the attack of amygdalitis the hearts had been sound, and it was presumable that such was also the case in the other instances. Mention was made of the frequency of such cases, and also of the occurrence of other members of the so-called "rheumatic series" after amygdalitis. It was stated that such amygdalitis and endocarditis are not rheumatic, but that the endocarditis is rather due to an infection by bacteria gaining access to the body through the tonsils, or to the toxins of such bacteria. Dr. James Tyson spoke of the frequency of nephritis originating in an attack of amygdalitis. Dr. W. S. Thayer, of Baltimore, stated that the fact that the tonsils may serve as the portal of entry for severe general infections is well illustrated by a case of acute fatal streptococcus infection that he had observed. Dr. W. S. Thomson cited a case of suppurative amygdalitis followed the day after rupture of the abscess by pleuritis, pericarditis, ulcerative endocarditis, ecchymotic spots, and death on the seventh day.

Sir F. Seymour Haden on the Other Side of the Germ Question.—Sir F. Seymour Haden, F. R. C. S., in the Milroy lecture on Proper and Improper Burial, has this to say about a side of the germ question which is in danger of being lost sight of. He refers in conclusion to another thing which has amounted to a profession of faith with him for many years, and which he observes has not escaped the acumen of Dr. Poore—the recognition of the inherent power of the individual to resist against the heaviest odds the convection of disease—a power evidently immeasurably greater than that

either of the *soi-disant* omnipresent microbe or of the artificial bacillus, however carefully it may be cultivated. He can not but think, with every respect for the praiseworthy efforts of the bacteriologist to track the morbid particle to its lair, and to master it there with its own weapons, that room still exists for a larger faith in those provisions of Nature for our individual protection than we are altogether willing to accord to them. If it is really a fact that, with every drop we drink and every mouthful we eat, we are taking in enough of the active principle of disease to destroy a regiment, and that, notwithstanding, we not only escape infection but are perpetually diminishing the zymotic death-rate, he finds himself, with Dr. Poore, obliged to accord a far greater value to this beneficent endowment of personal immunity than is commonly conceded to it.

The Pathological Appearances of Death from Lightning Stroke.—Bauer (*Münchener medizinische Wochenschrift*, No. 3, 1899; *Clinica moderna*, April 19th) relates the case of a man, twenty-five years of age, killed by lightning. At the autopsy were found a brown coloration of the blood, which had lost its tendency to coagulate, colored macule and burns upon the superficial cutaneous layers, anæmia of the brain, meningeal hæmorrhage, injection of the intestinal coils, and hyperæmia of the spleen.

The Difference in Effect between Criminal Abortion and Spontaneous Miscarriage.—Dr. Josephine L. Peavey (*Woman's Medical Journal*, June), in a paper read before the Denver Clinical Society, says that the after effects produced by a criminal abortion are far more serious than those of a spontaneous or accidental miscarriage, for in the latter, after the death of the fetus, a period intervenes before its expulsion, and the placenta undergoes fatty degeneration as at term, but in the former the fetus is forcibly separated from the uterus and there is usually imperfect delivery of the placenta and membranes, which may be followed by septic peritonitis and septicaemia. Displacements, diseased ovaries and tubes, metrorrhagia, and menorrhagia are a few of the evils which follow abortions, while to the dirty instruments and lack of care by the abortionist may be laid many a death.

Proceedings of Societies.

SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

Meeting of March 8, 1899.

The President, Dr. WILLIAM L. STOWELL, in the Chair.

Anæsthetic Leprosy.—Dr. GEORGE THOMAS JACKSON presented the case of a man, twenty-two years of age, who had suffered from the disease eight years. Dr. Jackson said that up to his thirteenth or fourteenth year the patient had lived in Battle, Montana. He came of healthy Irish parentage, and did not know where he had contracted the disease. For some years he had wandered about the country, but, as it usually took some years after infection for the disease to appear, he had probably been infected in child-

hood while living in Montana. The case was interesting for several reasons. In the first place, it was one of the rare cases of the disease developing in this country. In the second place, there had been no trouble with the mucous membrane of the nose, where the disease was apt first to show itself. In the third place, its lesions were not symmetrical. Generally there was a well-marked deformity of both hands; in this case only the right hand was markedly affected, while the disease was just beginning in the left hand. Instead of patches of a brownish color, there were rings, one ring extending from below the shoulder blades down to the buttocks. It looked like a huge ringworm with its scaly border. Anæsthesia had been found in limited areas. In many places the skin was hyperæsthetic. The ulna never could be felt more distinctly on the left than on the right side. The opportunity of seeing the patient was due to the courtesy of Dr. W. B. James.

Dr. A. E. GALLANT (by invitation) asked if the deformity of the hand partook of the nature of Dupuytren's contraction, or was a part of the present disease.

Dr. W. L. CAHEN asked as to the treatment of the disease.

Dr. JACKSON said that the deformity of the hand was characteristic of the disease. It was due to the atrophy of the interosseous muscles and of the skin. As to the prognosis, it was good in this part of the world, where the disease did not thrive. The patient should be encouraged to take a hopeful view of the case, and be placed under the best possible hygienic conditions. As to drugs, most reliance was to be placed upon chaulmoogra oil, nuxvomica, and iodoquin.

Some Observations upon the Surgical Anatomy of the Gall Bladder and Ducts.—Dr. GEORGE E. BREWER read a paper on this subject.

The writer presented a report of a hundred regional dissections made at the anatomical laboratory of Columbia University during the past eighteen months.

In these dissections he had noted the position of the gall bladder, its size, its method of peritoneal attachment to the liver, duodenum, or colon, and the presence of calculous disease or other pathological conditions. The cystic and common ducts were carefully measured, the permeability of the former ascertained, and the position of the duodenal orifice of the latter determined.

A constant fold of mucous membrane at the junction of the first and second portions of the duodenum was described by the writer. For this he proposed the name of the *falciform process* of the duodenal mucous membrane. It was found to have a fairly constant relationship to the duodenal orifice of the common duct, and could be relied upon as a valuable landmark when searching for the papilla during surgical operations in this region.

As a result of a number of dissections, the writer described certain external landmarks by which the position of the lower intercostal nerves could be readily located and avoided in incisions made for the purpose of exploring these organs.

A number of drawings were shown, illustrating the normal relations of the various structures, as well as certain vascular abnormalities.

The writer stated that the report was only a preliminary one, that the next treatise would be continued, and a complete report made at a later date.

At the close of his paper, Dr. Brewer exhibited several plates, showing the normal position of the gall ducts, hepatic artery, and portal vein, and also a num-

ber of variations from the normal in the origin and distribution of the hepatic and cystic arteries. He stated that in a series of dissections which he was making with reference to this point, he had found that in less than half the subjects examined did the hepatic artery correspond with the description found in text-books of anatomy. In his opinion, more variation was found here than in any other artery of the body.

The Symptoms of Gallstones.—Dr. W. L. BAXER read a paper on this subject.

The Diagnostic Value of the X Ray.—Dr. H. H. HAGAN said that some fourteen months ago he had a disputed case of what was supposed to be gallstones, and had invested in one of those induction coils for diagnostic purposes. He had exposed the patient and could not find the gallstone, but was well convinced that there was a gallstone there, and resorted to other means to find out what an X ray would do. He had taken a number of gallstones, six or seven, and had tried them, without placing the tissue, just as they were, and they would cast a little shadow, hardly as much as the flesh around the bone. He had imbedded them in tissue and they did not show at all. He had one stone given him by Dr. Burchell, who had taken it from a gall bladder while an interne in Bellevue Hospital. It was about as large as a pigeon's egg. That, being imbedded in hepatic tissue, had made a decided shadow. It had never occurred to him to break it into small pieces and expose it in that way, but probably it had contained a great deal more lime, instead of cholesterin. He did not think cholesterin would obstruct the light at all, but lime would, and practically the X ray had no value at all in gallstones.

Medical Treatment.—Dr. W. L. CARR read a paper on this subject. (See page 564.)

Surgical Treatment.—Dr. CARTER S. COLE read a paper on this subject. (See page 566.)

The PRESIDENT thought that the speakers had presented a number of phases of the subject, and some which were not entirely old. Certainly the surgical anatomy and anomalous conditions were quite new, and Dr. Hagan's experiments with the X ray, while negative, were valuable, showing how little one could depend on the X ray. In treatment, both surgical and medical, various suggestions had been made, and the general discussion of the subject had covered almost all except the aetiology. He believed that a large number of the cases were due to catarrhal affections of the ducts, which were caused by the great number and variety of germs there. He thought it would be interesting to know if those present had tried to treat patients in the intervals between the attacks, and had given them antisepsics to cure the catarrhal condition of the bladder and prevent the germs from thriving.

Dr. J. B. BISSELL said that the surgical part of the symposium had been gone over so thoroughly by Dr. Cole that there was not much to add. It seemed to him there were two or three interesting points that might be brought out from a surgeon's standpoint. The first was the indications for operation; and the second point, the immediate treatment of the wound following the operation. The indications for surgical interference were principally symptoms of absolute obstruction, acute suppurative, and long-continued jaundice; probably these three points would lead most surgeons to interfere. The interesting part of the immediate after-treatment was what to do with the wound after opening the gall bladder. Dr. Tait had left it open and drained in

over fifty of his cases; Elliott, who reported five cases in which he had operated personally, had sewed the bladder up, replaced it, and stitched up the wound of the abdominal wall. In the three cases that the speaker personally had had anything to do with, the edge of the open duct and bladder had been sewed to the wound and allowed to drain, the cavity having been packed with gauze. He thought this method would be preferable, because there were usually a number of stones in the duct; there was also a condition producing these stones, and the longer the duct was allowed to remain open the more likely were we to relieve the condition and get the stones out. He had never seen a fistula follow when the wound was left open. As to the protection of the abdominal cavity, it was always wise to bring the gall bladder immediately up into the opening and unite it to the edges of the wound in the abdominal wall. Of course, of itself, bile in the peritoneal cavity would do no harm, but possibly some of these stones might roll out without our knowledge.

Dr. H. H. SCHROEDER said he wished to speak of a form of treatment which was useful during the interim. We constantly saw statements coming from certain noted spas in Europe and this country concerning the wonderful solvent action of the mineral water of those places on stones in the gall and urinary bladders. The speaker had been for a while resident physician at the Glenwood Hot Springs, of Colorado, and he had seen nothing there to convince him of any solvent action whatever. Both he and his predecessor had patients who had gone there for treatment of gallstones. Those patients in whom the gallstones had been removed by surgical or other means had been much benefited; the general health had been restored, the catarrhal conditions of the intestinal mucous membranes had been overcome, and the various functions had been stimulated. The speaker attributed these results to drinking the water, which had acted as a laxative; to the invigorating climatic conditions; to strict dietetic treatment, and to regular habits while under observation. The cures in these cases had lasted longer than those usually experienced, even after the patients had returned to their former mode of living.

Dr. BAXER said that the treatment between the attacks was sometimes one of the most discouraging things in practice, when there were other stones in the gall bladder. The patients were put in the best possible condition to prevent the formation of new stones; they went to Carlsbad and took the treatment there for six weeks; they came back and lived a thoroughly hygienic life, and then, suddenly, there would be another crash, and in some cases they would get so discouraged that they absolutely refused to go on with the restricted diet. The treatment at Carlsbad and other mineral springs seemed to work well if the stones had not already formed before the treatment was begun, but, unfortunately, there was no way to judge whether the stones had formed or not. He had found it possible to give a very satisfactory Carlsbad course in New York by having the patients walk to the place in Central Park every morning for their glass of hot Carlsbad. In some cases it was remarkable how much benefit was to be derived from this regular exercise and system. Dr. Carr had spoken of the various solvents, and had mentioned oil incidentally, but not as one of the solvents. It was well known that oil dissolved gallstones if actually brought into contact. Practically, the speaker's experience with oil had not been good, but theoretically he thought that if the stone was lodged in the duct just at the point where

the duct entered the duodenum—and this was, in fact, a very narrow part of the duct—the oil might be able to reach it and exercise a certain amount of solvent action. In his experience the giving of oil had not been uniformly beneficial. It had sometimes upset the stomach and had caused more trouble than good. With regard to the treatment of an acute attack, Dr. Carr had not spoken of the time-honored custom of putting the patient in a hot bath, which often gave much relief. In the use of morphine he favored the practice of giving rather more than a quarter of a grain at the first injection, as less would actually be needed in the long run than where the smaller dose was given at first.

Dr. GALLANT said, in reference to the water of the Glenwood Springs, Colorado, that at ten o'clock one evening last June he had gone down into the swimming pool and had enjoyed a hot bath, and if the effect on gallstones was as good as the taste of the water was bad, he thought it must be very efficacious. Dr. Cole mentioned that cases of abscesses in the pelvis, which arose from the gall bladder, had been reported. The following case which the speaker, as an assistant, had seen, was of that character: The diagnosis of appendicitis, from the symptoms which usually accompanied that disease, had been made. There had been no previous history of gallstones, and preparations for the operation had been made with the idea of taking out the appendix. While he had been scrubbing up the patient he had noticed that the whole right side was tense, extending from the pelvis up under the ribs, as if filled by a large tumor, to which he had called the attention of the surgeon. The surgeon had first made a small median incision, through which to determine the size of the tumor, and the best point for drainage. He had found it in contact with the abdominal wall, midway between the umbilicus and the anterior superior spine. The median incision had then been closed, and a second incision made directly down to the tumor; the opening had been packed with gauze that adhesions might take place between the abdominal peritoneum and the tumor. Twenty-four hours later a small incision had been made into the tumor and a quart of what looked like dirty-brown cream had drained off. A drain had been placed in the opening, which the next day was enlarged enough to admit the finger, and to their surprise another quart of the same liquid had drained away, and with it twenty-two gallstones. The patient had done well and within a few months the opening had closed. So far as was known, the patient had never had any further symptoms. Three other cases of gall-bladder disease, which the speaker had seen, had been treated by the open method—viz., sewing the gall bladder to the peritoneum, incision into the gall bladder, allowing it to drain. The fistula, without suture, had gradually closed.

Dr. Carr spoke of some symptoms that had not been mentioned. First: He had been surprised in a number of instances to find fine rales at the base of the right lung. In one case of gall-stone colic crepitation had lasted twelve hours. The patient was a stout man and had had a previous attack. There might be some explanation of these cases in connection with the interference of circulation at the base of the lung, which was, perhaps, accounted for by the ascending pain and the limited action of the diaphragm on that side. Second: The symptom of jaundice was in some instances an uncertain one; one looked for jaundice when there was an obstruction, but jaundice was noted so often after operation, where no stones had been found except biliary con-

stones, masses about the size of a pinhead, that it would seem as if it was not always necessary to have complete occlusion. Jaundice was also found where stones were in the hepatic duct and pressed against the common duct. In the matter of treatment, he called attention to the fact that the so-called dissolving treatment of various drugs was much overestimated, and while for a great many years the French, English, and all competent observers made use of chloroform, ether, turpentine, and sweet oil, these drugs did not dissolve the stones. They did some good in increasing peristalsis; especially the sweet oil. If sweet oil increased peristalsis, there was a greater flow of bile, expulsion of stones in some cases, and a better condition of the intestine, because the intestine was made more antiseptic. It could hardly be made aseptic in those cases. The commonest causative factor in the formation of these stones was undoubtedly the *Bacterium coli commune*. There was no doubt that anything that increased peristalsis eliminated causes of catarrh in the intestine and lessened the formation of calculi. Medicinal treatment alone was unavailable. A great many patients could be cured by systematic management, but they so often overstepped the bounds, took salads and late suppers, that the stones would reform, because they would have unnatural conditions brought about with the resulting changes to the gall bladder. When the disease reached a point where the patient was not relieved, either by general management or drugs, surgical means should be considered; but, so far as he could learn from the works on this particular branch of surgery and by conversation with men who had done the work, a great many patients had been operated upon in whom the gallstones had been so small and insignificant that it was a question whether the conditions that called for the operation were definitely studied, and it looked as if it would be necessary to have a more exact diagnosis of calculi before operation could be proposed in a general way to take the place of continued medical treatment and observation.

Dr. Cole said he would like to thank the gentleman who had presented the article on anatomy, and particularly in regard to the arterial distribution. He agreed entirely with Dr. Bissell as to the indications for operation, and so stated them in the paper: that where attacks occurred, when the jaundice was persistent and where the medical measures were not of any value apparently, operation was absolutely demanded, and the sooner the operation the better the chances for recovery. The same was true in a general way of all surgical procedures. In his own experience olive oil administered in large doses had been beneficial, and he had repeatedly given it to patients with acute biliary attacks. When they had retained it and the oil had gone through, the stones had done the same thing. He spoke of a patient who, after having taken a teaspoonful of olive oil, had passed a number of good sized stones. The physician who had treated the case stated that there had been eighty or ninety stones passed by the bowel after this dose of olive oil. About two or three years ago a gentleman had come to his apartment about three o'clock in the morning with quite an acute attack of biliary colic. The speaker had given him a hypodermic injection of morphine, relieved his pain, and sent him home, telling him to take a big dose of olive oil, which he had done, and he had recovered from the attack, passed the stone without any trouble, and had not had an attack since. The preventive treatment by the cholagogue of sodium seemed, by an examination of the litera-

ture, to offer the best chances, and the cases that had been followed up appeared to have done better, though there were not a great many cases recorded. Of course, general hygiene was the essential point in the after-treatment.

Dr. D. E. WALKER said that some years ago he had had a patient who had had frequent attacks of gallstone colic, and in whom he had found a very perceptible tumor in the gall bladder. An operation had been suggested, but she had been advised to take large doses of olive oil first, and after having used that a few days she had passed by the bowel over a hundred gallstones. The tumor had disappeared from the gall bladder and the patient had had no attack of colic since. He had had a case recently in which the attack had come on immediately after a hot bath. Dr. Baner had spoken of hot baths as being, probably, a good thing in the treatment of a case, and the speaker agreed with him, because it would bring on a relaxation of the walls of the cystic duct, and that was probably the explanation of the attack in that case. There had probably been a stone in the gall bladder, and it had entered the duct at that time and had brought on an attack of gallstone colic.

Dr. GEORGE H. MALLETT said that what he had to say was in regard to some difficulties in making a diagnosis. He was especially disappointed in Dr. Hagan's researches. He had a patient under his care who had been to five different eminent men, and to some intestinal specialists; but they had not been able to determine what was the matter. Last summer a patient who presented a large tumor, probably as large as a small fist, as near to McBurney's point as it could be located, had come to the hospital. Five other specialists had been consulted in this case, and the diagnosis had varied from appendicitis to fecal masses, floating kidneys, and sarcoma. Finally, they had weeded down and thought possibly it was a floating kidney or gallstone. The only symptoms the woman had given were bearing-down pains and loss of flesh, and the skin was particularly dry. An incision had been made over the mass, which had proved to be the gall bladder; there was found a very long neck and they had removed about six hard stones and an enormous quantity of small gallstones. Nothing had come of it, and the wound had healed and the woman had recovered. He was inclined to doubt the number of stones spoken of as being passed after taking oil. He had seen patients pass a number of stones, with no history of gall-bladder trouble.

Dr. BREWER stated that he was surprised that no one had mentioned the new and ingenious operation recently suggested to the profession by Dr. McBurney, which consisted in opening the second portion of the duodenum and removing the calculus through the duodenal orifice of the bile duct. In his paper he had attempted to point out certain landmarks which would materially assist the surgeon in locating the papilla in case the stone was not impacted at that point. He cited a case which had come under his observation last summer at the City Hospital, in which he had found, on examination, only a small, hard, movable nodule to the outer, right side of the umbilicus. Upon opening the abdominal cavity, this nodule had been found to be a small carcinoma of the fundus of a very movable gall bladder, the mobility of the organ having been due to the presence of a mesentery which connected it with the liver, similar to those described in the paper. The entire gall bladder and an inch of the cystic duct had been removed. The patient had made a complete recovery, but had died six or eight

months later, probably from a recurrence. He cited another case which he had seen in consultation with his colleague, Dr. Kelly. In this case Dr. Kelly had utilized an old biliary fistulous tract for the reestablishment of a communication between the hepatic ducts and the duodenum. Dr. Kelly had excised the fistula and had implanted the cutaneous extremity into the duodenum. The patient had made a complete recovery, and had been relieved of an infirmity which had been thought by many to be incurable.

Miscellany.

What General Wood has done for Santiago.—We do not often reproduce things wholesale, but the present account of the great work accomplished by General Wood in Santiago, coming, as it does, from a foreign source (*Medical Review of Reviews*, May, citing the *Fortnightly Review*) is so gratifying that we can not refrain from reproducing it *in extenso*. The *Review* says:

"Sanitary reform in Cuba is not the least important of the scientific work being carried out under American auspices in their newly acquired territory. Under Spanish rule, Santiago had established an unequaled reputation for insanitation, and General Leonard Wood, M. D., of the United States Volunteers, when appointed governor, found the city in an indescribably filthy condition, its normal state having been aggravated by the horrors of the siege. Immediately upon assuming control of the district, the insanitary condition of the city was one of the first measures that received General Wood's attention. Under his administration, the daily death-rate has fallen from two hundred to ten, and the inhabitants have been rescued from a system that tended to reduce them to beggary. The old abuses that turned the law courts into inquisitions and the customhouse into a treasury for a privileged class have been swept away; and Santiago, with its clean streets and free press, is in a fair way to become one of the most healthy as well as one of the most beautiful cities in the New World. It is a generally current fallacy that the average medical man is unsuited for any pursuit other than the practice of his profession. As a rule, he is not considered a good man of business, and he is rarely, in this country at least, appointed to important positions of administrative control. The story, however, told by Mr. H. H. Lewis, in a recent number of the *Fortnightly*, of General Wood's remarkable work at Santiago, is a striking picture of what a medical man can accomplish when appointed to an important administrative position. This glowing tribute to the capabilities and noble character of an Anglo-Saxon physician can not, we think, fail to be of interest to every English-speaking member of the medical profession, and we are glad of an opportunity to quote, somewhat at length, the summary in the *Review of Reviews* of Mr. Lewis's article. As Mr. Stead has said, the story of General Wood at Santiago is a tale of modern chivalry that stirs the blood of every true lover of his kind. 'Hero as a Scavenger,' as Carlyle might have termed him, is the title given to the ex-colonel of the Rough Riders and the present Governor of Santiago. The writer says: "If ever in this world the extraordinary man, the

man of destiny, the man of preeminent power and resource, was needed, it was in Santiago de Cuba during the latter part of July, 1898. The occasion demanded first a physician, to deal with the tremendous sanitary needs; then a soldier, to suppress turbulence and effect a quick restoration of law and order; and, finally, a statesman, to re-establish and perfect the civil government. In General Wood was found a man who, by nature, education, and experience, combined in himself a generous share of the special skill of all these three. As in Havana, the Augean stables were here completely outdone. For two centuries Santiago had borne the reputation of being one of the most unclean cities on earth. Of it an old merchant captain had said, 'It could be smelt ten miles at sea.' When General Wood assumed the government of Santiago on the 20th day of last July, its streets and courts and houses had come to the last degree of filth and noisomeness, and of its forty odd thousand residents great numbers were sick, no small number were starving, and all were utterly miserable. Bodies of the dead lay in the streets, and as the new governor rode about the city, making his first inspection, vultures flew up before him from feasting on human carcases. Within a few hours of the receipt of his appointment he had thrown off his coat and was heartily at work. Happily for the quick and sure execution of his task, he began with ample powers. The matters that first claimed his attention were the feeding of the starving people and the amendment of the city's sanitary condition. As many rations as could be obtained were issued with a free but careful hand; food depots were established at various places; and before forty-eight hours had passed actual famine had been brought to an end. But as the supply of food increased through the ordinary channels of trade, the prices did not decrease. General Wood accordingly sent for the butchers and demanded from them the price at which they bought the meat they were selling at ninety cents a pound. After futile attempts at evasion, they confessed they paid only fifteen cents a pound. The general promptly informed them the selling price must go down from ninety to twenty-five cents; and go down it immediately did. Other food prices quickly followed.

"What is described as 'Santiago's first cleaning' was next taken in hand. The city was one vast charnel house and cesspool combined. In all the interior courts there were cesspools, and these were almost never emptied, and became fountains of foulness and disease. Even in the houses there was the grossest uncleanness. In many of them, owing to the recent stress of epidemic and starvation, were found decaying human bodies; ten were found in a single house. The clouds of vultures, voracious as they were, found the human meat too plentiful; theiravings filled houses and streets with nauseous corruption. The death rate, at ways high in Santiago, became at this time about two hundred a day. In his first proceedings against this unspeakable squalor General Wood received but little aid or sympathy from either Spaniards or Cubans. The neglected human dead were, however, soon carted outside the city, heaped into piles, sprinkled with kerosene, and burned. In one funeral pyre even bodies were consumed. It reputedly must have been in darkness and daylight to clear one street. After a few days, a house to house sanitary inspection was made, and the householders were notified that all cesspools

must be emptied without delay. Then an order was issued calling upon the housekeepers to collect their household garbage in boxes or barrels for the wagons that were sent round in the early morning to haul it away. At first there was some demur to the new method; but sharp words, threats, and in some cases actual corporal punishment brought it into general observance, and now the householders of Santiago vie with each other in having their garbage boxes ready for the call of the street-cleaners' carts. More serious opposition was caused by the introduction of disinfectants; this caused open rebellion. The previous odors—time-honored and, as it were, the custom of the country—were preferred to the odor of chloride of lime. It was scattered, nevertheless, with a liberal hand, and now requests for disinfectants are received daily by the health department. Moreover, people are beginning to notify the sanitary officer of the existence of unclean cesspools maintained by their neighbors.

"The streets had never been properly laid, and the heavy army wagons had churned the atrocious roadways into rivers of liquid mud. A circle was drawn about the city, and a line through the centre. The line was Marine Street, and part of the circle represented the water front, along which was a really beautiful and picturesque drive, known as the 'Alameda.' 'Build a boulevard where I have drawn the circle, and pave Marine Street. Hire Cubans; pay them fifty cents and a ration a day,' ordered General Wood. The boulevard is in course of construction, and Marine Street is being paved. After burying the dead, emptying the cesspools, paving the streets, and arranging for a better water supply came other reforms. The new administration made important changes in the school system, including the severing of the schools from the church, and the introduction of English into the curriculum; established a rural police force, and effected a temporary suspension of mortgage foreclosures to enable the small farmers to recover from the effects of the war. The jail was the lair of shameful injustice, and the very home of Yellow Jack. Poor wretches had been shut up without trial for years—one man for ten years simply 'at the will of the governor-general.' They were promptly liberated. Henceforth no prisoner is detained forty-eight hours without either a trial or an investigation.

"These drastic reforms aroused considerable opposition. A riot broke out at San Luis, a town twenty miles out. General Wood heard of the riot while he was down with fever. Ill as he was, he ordered his carriage, drove to the telegraph office, and for three hours dictated instructions. Next day, still racked with fever, he went to San Luis and investigated matters on the spot. On September 22 a mob of infuriated Cubans attacked the Spanish Club, opposite General Wood's office, where he was sitting writing, defended by a solitary sentinel. He picked up his riding whip and, accompanied by the one soldier, strolled across to the scene of the trouble. The Spaniards in the club had closed the door, but the excited Cubans were trying to force a way in by the side entrance. 'Just shove them back, sentinel,' and General Wood entered. Around among the tables a war was cleared in front of the door. Now that the fighting was over, he placed his foot upon that which he called a 'snail's pace' and deliberate manner. He then turned and directed the sentinel to write, 'The mob dispersed, subdued by two men, one rifle, and a riding whip.'

"The change effected by this Paladin of the dust cart in four months is thus summarized by Mr. Lewis: The rescue of the population from starvation to a fair satisfaction of all their daily necessities. The conversion of one of the foulest cities on earth to one of the cleanest. The reduction of an average daily death-rate of two hundred down to ten. A considerable progress in a scheme of street and road improvement that will add immensely to the convenience and beauty of the city. A radical reform in the customhouse service, resulting in increased revenues. A reduction in the municipal expenses. The correction of numerous abuses in the management of jails and hospitals, and in the care of the inmates. The liberation of many prisoners held on trivial or no charges. The reformation of the courts and a strict maintenance of law and order. The freedom of the press. A restoration of business confidence, and a recovery of trade and industry from utter stagnation to healthy activity.

"General Wood's career as military governor of the province of Santiago de Cuba is a conspicuous example of the special fitness for administrative work, under new conditions, developed by a medical training. General Wood, who is but thirty-eight years of age, graduated at Harvard in 1882. He subsequently joined the army as a contract surgeon, and took part in several campaigns against the Apaches in Arizona and New Mexico. When the war with Spain broke out, he was an assistant surgeon in the United States army, with the rank of captain. He was stationed at Washington at the time, and, together with Governor Roosevelt, raised a regiment of cavalry, of which Wood was to be colonel and Roosevelt lieutenant colonel. This is the regiment which, as the 'Rough Riders,' won for itself such distinction in Cuba."

How to Make Paper Waterproof.—To the physician, especially to the one practising in out-of-the-way places, the following simple method, quoted by the *Sanitarian* for June from the *Journal of the Franklin Institute*, may prove useful: The German journal *Neueste Erfindungen* describes the following method of making a waterproof paper: The sheet is coated on both sides with a solution consisting of one part gelatine, four parts water, and one part glycerin. When dry, the paper is immersed in a ten-per-cent. solution of formalin. After this treatment the paper is said to become impervious even to steam.

Trained Nurses for Epileptics.—Dr. William P. Spratling, medical superintendent of the Craig Colony for Epileptics, at Sonoma, N. Y., established two years and a half ago a training school for nurses. The course embraces the subjects usually taught in such training schools, and, in addition, special attention is paid to epilepsy.

The school held its first graduation exercises on the evening of June 5, 1899, a class of eleven, seven men and four women, graduating at that time. Fifteen students received first-year certificates at the same time.

Treatment of the Abdominal Viscera through the Colon.—At the recent meeting of the American Medical Association, held in Columbus, Dr. Fenton B. Turk, of Chicago, read before the Section in Medicine a paper of which the following is an abstract:

The intimate relation of the hepatic, splenic, and sigmoid flexures and the transverse colon with the liver,

duodenum, kidney, and pelvic organs makes it possible to influence these organs and the metabolism of the body through the colon by the direct application of heat, cold, electricity, and other physical stimuli. In discussing such treatment, we will consider (1) the direct effect in removing pathological conditions of the colon; (2) the effect of contiguity with other viscera; (3) the reflexes.

The most frequent indication for treating the colon is for evacuating retained contents. Employing large quantities of water, salts, glycerin, or soaps may afford relief, but in chronic diseases they are not only inadequate but harmful. The muscular walls and mucous membrane may both be diseased, necessitating direct remedial applications. Heat relatively high, directly applied to the mucous membrane, immediately stimulates the vasomotor centres, raising the blood pressure, stimulating the kidneys, increasing the hepatic function, inducing leucocytosis, and accelerating metabolism, oxidation, and elimination. The methods of treatment employed are (1) hydrotherapy; (2) hot and cold air; (3) massage; (4) electricity; (5) medication; (6) dietetics.

The position, elevating the hips high in the dorsal posture upon a table devised for the purpose of raising the patient to any angle, is a very important consideration. From two hundred and fifty to three hundred cubic centimetres of water at 122° F. are passed into the colon three or four times, each quantity being allowed to run off before more is introduced. The treatment is continued with water at 125.6°, increased to 131°, using in all from three to six quarts. The patient is then sent to the toilet room, after which the treatment is repeated.

Experiments upon dogs have been conducted as follows: The abdomen is opened under local and partial general anesthesia. The viscera are exposed to cold draughts until there is a fall of blood pressure approaching collapse. Water at 122° is then introduced into the colon for five minutes without marked change. The water is withdrawn, and the animal allowed to pass into collapse, when the viscera are of a bluish shade and the vessels congested and tortuous. Water at 131° is introduced for one minute, and then withdrawn. This procedure is repeated several times, during which the blood pressure gradually rises, and within ten minutes the animal is out of shock and recovers.

Daily observations and comparisons made upon patients show circulatory effects verified by the sphygmograph and sphygmometer; blood changes—(a) noticeable increase of red corpuscles, (b) leucocytes markedly increased; effects upon gastro-intestinal tract, kidney, and liver; effects upon the temperature of the mouth, skin, and stomach, and upon the pelvic organs; and an action on elimination and self-intoxication, and general metabolism.

As regards the gastro-intestinal effect, there are at first local contractions, generally followed by peristaltic and antiperistaltic movements of the small intestines. The kidneys are stimulated to secretion within three minutes. The bile is increased in proportion to the excretion of urea. Metabolism, destructive and constructive, is influenced by impulses in the same nerve, either singly or both at the same time.

Colonic lavage in all forms of pelvic congestion is invaluable, and the water is borne at a higher temperature than in the vagina. Self-intoxication may evidently originate through functional inactivity in the gastro-

intestinal tract, liver, kidneys, skin, and lungs. In the gastro-intestinal tract it is of more frequent occurrence than is commonly supposed. Acute gastro-enteritis is relatively rare, but chronic gastro-intestinal atony is quite common, resulting in various symptoms of self-intoxication.

The liver, either by producing toxic material or by failing to take care of the toxins passing through it, as in cases of catarrhal inflammation of the bile ducts, contributes to the result.

The American Proctological Society was organized on June 7th, and the following-named gentlemen were elected officers: Dr. Joseph M. Mathews, of Louisville, president; Dr. James P. Tuttle, of New York, vice-president; Dr. William M. Beach, of Pittsburgh, secretary and treasurer; and Dr. Samuel T. Earle, of Baltimore, Dr. A. Bennett Cooke, of Nashville, and Dr. J. Royal Pennington, of Chicago, councillors.

Death of Dr. Richard B. Westledge at Manila.—

From the *Dubuque Daily Times* for June 11th we learn of the death of Dr. Richard B. Westledge, first lieutenant of the Third United States Infantry, at Manila. Dr. Westledge left a good practice in Dubuque to serve in the war. He leaves a widow, at present in California.

The Future of the Woman Physician.—At the graduation exercises of the Women's Medical College of the New York Infirmary, on Thursday evening, May 25th, Dr. Frederick Peterson, clinical professor of insanity, made a brief address to the class of 1899, from which we make the following extracts:

There is something inspiring in seeing a battalion of troops going forth to the wars, and if we look at it aright there is even greater inspiration in observing a company of young physicians setting out for a lifetime of continuous battle against the diseases and disorders which afflict mankind. The warlike conquerors, on the one hand, march out to slay their own kind, but the "conquerors of peace," as they have been well named, give battle to other foes, to the invisible enemies that wear the garb of many a perilous disease, and set forth not to kill but to save their fellow men. In the stories of the ancient wars there are traditions that companies of women sometimes took arms and fought desperate fights on bloody fields. In these more peaceful battles of modern times to which I have just referred we witness the onslaughts of phalanxes of new Amazons which make annual sorties from our medical schools for women. In the end the "conquerors of peace" will prevail, and not a few of the laurels of victory will belong to the women who have bravely borne a notable part in the strife against disease.

With the gradual progress of civilization, with the slow but sure evolution of society, the work of the woman physician must unfold and broaden to an extent undreamed of now. At the present time her professional duties are chiefly among women and children, but there are already indications of wider fields of labor. To the delicate manipulations of laboratory research she can bring such deft and skilful fingers that a man's awkward hands seem like the flippers of a seal in comparison. Centuries of fine needlework, crocheting, and embroidery have prepared those fingers for section-cutting, staining, and the innumerable synthetic and analytical processes now started to modern methods of scientific research. She brings also to

science the intuitive wit, the swift imagination, the deductive methods of philosophy which Buckle so lauded in his essay on *The Influence of Women on the Progress of Knowledge*. This writer gives his reasons for affirming that women are more deductive than men: "First, because they are quicker than men. Secondly, because, being more emotional and enthusiastic, they live in a more ideal world, and therefore prefer a method of inquiry which proceeds from ideas to facts; leaving to men the opposite method of proceeding from facts to ideas." He goes on to say that "women have rendered great though unconscious service to science by encouraging and keeping alive this habit of deductive thought, and that, if it were not for them, scientific men would be much too inductive, and the progress of our knowledge would be hindered."

But this service to science rendered by women is now no longer unconscious, as Buckle described it at the time he wrote this essay, over forty years ago. It is a fully conscious service, as is evidenced by the very creditable work of women at the present time in many branches of science. There is a real place for the women who graduate as doctors, but do not care to practise the art of medicine, in our laboratories for pathology, chemistry, physiology, psychophysics, and the like, and physicians of both sexes are fast beginning to appreciate the peculiar fitness of women for work of this kind.

And this is not by any means the whole domain over which the woman physician may yet come to rule. There is a particularly feminine quality which will ultimately serve her in still another important sphere of activity. All these centuries of domestic occupation, before woman entered upon her commercial and professional career, have bred in her an instinctive love of cleanliness and beauty. As a physician she does not lose that innate sense of orderliness, neatness, cleanliness, nor does she give up the hereditary desire to surround herself with what is pleasing and attractive. Let the woman who becomes a physician but extend the art of which she has such peculiar knowledge, that of making the home clean and charming, to circles reaching far beyond the home, to the streets, to the towns, and to the cities, and what vistas for well-doing will open up before her! In other words, I should like to see well-trained women physicians on our public boards of health. As women and as physicians you will some day come into your own, and expand the principality of your tidy, healthful, and beautiful home into the wide kingdom of public health and hygiene. Our streets will be thoroughly clean, our water supplies and methods of sewage-disposal perfect, our thoroughfares sprinkled and shaded, our pavements improved, our factories made healthful, our public baths and parks multiplied, the homes of the poor redeemed from squalor, and you shall go with all the paraphernalia of modern Amazons into the darkest places to fight and conquer the pestilence that walks therein.

But this may bring you into politics! Well, there was a noted statesman who addressed the Academy of Medicine a few years ago, and in his address he spoke of the diseases of the body politic, which physicians in general were prone to neglect. He strongly urged physicians to awaken to a sense of their own responsibilities toward the diseases which afflicted the body politic. Doctors as a class are more careful of their civic duties than in other circles of the community. They should begin to study, clearly and conscientiously, the diseases of the body and to see to the end that some happy

therapy may bring about regeneration. The women physicians can further this work with hand and voice and, it may be, votes.

The Harlem Medical Association.—At a meeting held on June 12th officers for the ensuing year were elected as follows: President, Dr. Henry W. Mooney; vice-president, Dr. Montrose R. Richard; secretary, Dr. Joseph E. Lombard; treasurer, Dr. William F. Farrell; trustees, Dr. David Franklin, Dr. Samuel Gibbs, and Dr. Henry Heiman.

The following resolution was also passed:

Resolved, That the members of the Harlem Medical Association having heard with deep regret of the death of their late associate, Dr. Henry E. Crampton, desire hereby to express their appreciation of his upright, kindly, and cheerful character and of the great loss which the profession has suffered in the untimely removal of one of its members who was more than ordinarily prominent in many fields of usefulness to his fellow man outside of the purely professional round of duties.

The association desires further to express the deepest sympathy with the near relatives of the doctor, upon whom the loss of husband and father falls most heavily, and who could best appreciate the beauty and sweetness of his character.

[Signed.] RICHARD VAN SANTVOORD, M. D.,

Chairman;

J. T. JOSEPH BIRD, M. D.,

JOSEPH E. LOMBARD, M. D.,

Committee.

Preliminary Report on the Tuberculosis Congress.

The congress was held in Berlin from May 21th to May 27th, in the Reichstag Building, and the opening session took place in the presence of the Emperor and other high German officials. The most prominent German physicians, hygienists, and bacteriologists were present, as well as representatives of the leading medical nations from England, France, Russia, Italy, Denmark, Austria, Japan, Spain, etc.

The papers presented by the most prominent men were very thorough and were complete reviews of our present knowledge of tuberculosis, both from the scientific and the practical standpoints. The special object for which the congress was called—namely, the purpose of arousing interest in the erection of sanatoria for the tuberculous poor, especially the working classes—will, it is hoped, be greatly advanced. According to the present German laws, each laborer and each employer of a laborer is required to pay a very small tax, which is subsequently utilized in taking care of the tuberculous poor. In this way quite a large fund has been secured, and at the present time there are fifty sanatoria in the German Empire in which the poorer and laboring classes can be treated; and a double purpose is thus, moreover, served, namely, the improvement of the health of the individuals and at the same time their education in sanitary matters.

While there may not be any direct practical results from this congress, there will be many indirect ones.

The papers presented by two well-known bacteriologists upon the ways in which tuberculosis is contracted, especially from the dust, were very complete and satisfactory. While a number of papers upon different methods of treatment were read, it can be said that as yet no method has been presented which has given better

results than those methods which are used in our own sanatoria, or better results than those secured in many sanatoria where no special method of medical treatment is followed. There were over two thousand members of the congress and over two hundred official delegates from the various States of the German Empire and the countries before mentioned.

One of the most important things in checking the spread of tuberculosis in all countries is to educate the people thoroughly in regard to the different ways in which tuberculosis may be contracted and the great danger of associating with tuberculous individuals. In other words, the people generally must be thoroughly educated in hygienic matters. Congresses of the same character as the one just held in Berlin help a great deal in this general education and in exciting interest, and are therefore productive of great good. Similar movements which have been started in America should be encouraged. When the officials and prominent people of a government take an active interest in a congress of this sort, as has been done in Germany by the Emperor and Empress, more general interest, and consequently more good, naturally results. The official delegates from the United States were cordially received and entertained with the utmost courtesy. Several very valuable monographs were presented to the congress, one especially upon German sanatoria by Dr. Panwitz, general secretary of this congress, which are well worth careful examination. Dr. Panwitz will be very glad to send copies of his monograph as well as other similar papers to physicians who are especially interested in the erection and equipment of sanatoria for consumptives. A letter addressed to the Central Bureau of the Tuberculosis Congress, Wilhelmsplatz 2, Berlin, will receive prompt attention.

E. A. VON SCHWEINITZ, M. D.,

Delegate for the United States to Tuberculosis Congress.

The Alumnae Association of the Northwestern University Woman's Medical School held its nineteenth annual meeting on June 15th at the Woman's Medical School, 337 S. Lincoln Street, Chicago, Illinois. Dr. Julia Cole-Blackman, Geneva, Illinois, was elected president; Dr. Eliza H. Root, secretary, and Dr. Mary C. Hollister was reelected treasurer. The reports of the treasurer and the various committees showed the association's condition to be one of prosperity. The appointment of Dr. Marie J. Mergler, one of the alumnae, as dean of alma mater was indorsed, and the university authorities were thanked for the appointment. The Earle Memorial Library reported five hundred volumes on its shelves, a very satisfactory growth for the short period elapsed since its foundation.

An Expedition to West Africa to Investigate Malarial Disease.—From the *Evening Post* for June 17th we learn that the newly formed School of Tropical Diseases at Liverpool, England, will dispatch an expedition to Sierra Leone early in August to investigate the causes of malarial and other indigenous diseases. Major Ross, of the Royal Army Medical Corps, is to head the expedition, and intends to continue the methods he used when similarly employed by the Indian Government.

Mount Sinai Hospital.—Dr. Joseph Wiener, Jr., has been appointed adjunct attending surgeon to the hospital.
